 1. The Assessment Includes a Broader Range of Mine Scenarios..... 13

 2. Mitigation Measures Are Insufficient to Avoid Unacceptable Adverse Effects, Even Including “Best Practices” 14

 a) Unavoidable Habitat and Flow Losses Cannot be Mitigated..... 15

 b) Impacts from Mine Operations and Maintenance Cannot be Adequately Mitigated 16

 c) Direct and Indirect Loss to Alaska Native Subsistence Uses Cannot be Mitigated..... 18

 3. Expected Future Climate Change Increases the Long-Term Risk of Unacceptable Adverse Effects 19

 4. The Hydrologic Nature of the Watershed Would Magnify the Unacceptable Adverse Effects and Unpredictable Impacts of Mining 20

 5. “Day-to-Day” Water Treatment and Transportation Corridor Operations Would Cause Unacceptable Adverse Effects in Bristol Bay 21

 a) Leachate Escape and Treatment Failure are Foreseeable 22

b) Additional “Day-to-Day” Adverse Effects will Result from Temperature Modifications and Operation of the Transportation Corridor	24
6. Unacceptable Cumulative and Induced Impacts are Reasonably Foreseeable	26
a) Cumulative Effects of Additional Mine Development Call for 404(c) Action	27
b) Additional Development Induced by Mining Would Further Magnify the Adverse Effects on Bristol Bay	28
IV. THE BRISTOL BAY ECOSYSTEMS SHOULD NOT BE LEFT IN THE HANDS OF MINING COMPANIES THAT HAVE MISLED THE PUBLIC, THEIR INVESTORS, AND EPA.....	28
V. CONCLUSION.....	31
APPENDIX A.....	33
APPENDIX B.....	111

I. INTRODUCTION

On behalf of its 1.4 million members and activists, the Natural Resources Defense Council (“NRDC”) is pleased to submit these comments to the U.S. Environmental Protection Agency (“EPA”) regarding the agency’s April 26, 2013 second Draft Assessment of Potential Mining Impacts on Salmon Ecosystems of Bristol Bay (“Watershed Assessment” or “Assessment”).¹ The Assessment was prepared pursuant to EPA’s authority under Section 104 of the Clean Water Act. The agency released its first Assessment in May 2012, two years after receiving petitions under Section 404(c) of the Clean Water Act for EPA action to prohibit, deny, restrict, or withdraw the specification of the proposed Pebble Mine site in Bristol Bay, Alaska as a disposal area for the discharge of dredged or fill mining material. EPA subsequently held numerous public hearings, considered 233,000 public comments (over 90% in support), consulted with tribes, and received input from a peer review panel of 12 independent scientific experts before releasing this second draft Watershed Assessment in April 2013.

The Bristol Bay watershed – and the salmonid, wildlife, and native communities that call it home – exist in a rare and pristine state of self-sustainability, undisturbed by significant human development. Large-scale human impacts are absent, and the watershed forms part of one of the last remaining virtually roadless areas in the United States. Bristol Bay is home to the largest sockeye salmon fishery in the world, supporting half of the world’s wild sockeye salmon and generating \$1.5 billion annually.² Approximately 70% of the salmon returning to spawn are harvested, and the commercial salmon harvest has been successfully regulated to maintain a sustainable fishery and, in turn, sustainable salmon-based ecosystems. The Bristol Bay watershed, and its high quality commercial, recreational, and subsistence fisheries, represent an aquatic resource of national – and global – importance.

¹ NATURAL RES. DEFENSE COUNCIL (“NRDC”), COMMENTS ON BEHALF OF THE NATURAL RES. DEFENSE COUNCIL ON THE U.S. ENVTL. PROT. AGENCY DRAFT BRISTOL BAY WATERSHED ASSESSMENT (July 23, 2012) are attached hereto as Appendix A. In addition, we incorporate by reference JOHNNIE N. MOORE, REVIEW OF REPORT EPA 910-R-12-004BA: AN ASSESSMENT OF POTENTIAL MINING IMPACTS ON SALMON ECOSYSTEMS OF BRISTOL BAY, ALASKA (May 17, 2013) [hereinafter “MOORE”]; DAVID M. CHAMBERS, CTR. FOR SCI. IN PUB. PARTICIPATION, COMMENTS ON DOCKET #EPA-HQ-ORD-2013-0189 (June 28, 2013) [hereinafter, “CHAMBERS”]; Letter from John Boreman, Am. Fisheries Soc’y, to Office of Env’tl. Info., U.S. Env’tl. Prot. Agency (“EPA”) (May 30, 2013); Letter from Nicole Lederer, E2 Co-Founder, Env’tl. Entrepreneurs, to Office of Env’tl. Info., EPA (June 10, 2013); CTR. FOR SCI. IN PUB. PARTICIPATION, CRITIQUE OF N. DYNASTY’S PROPOSED MITIGATION STRATEGIES (June 26, 2013); GEORGE PERIDAS, DEPUTY DIRECTOR, SCI. CTR., NRDC, COMMENTS OF THE NATURAL RES. DEFENSE COUNCIL SCI. CTR. ON EPA’S REVISED DRAFT ASSESSMENT OF POTENTIAL MINING IMPACTS ON SALMON ECOSYSTEMS OF BRISTOL BAY, ALASKA (June 28, 2013) (on file with author).

² GUNNAR KNAPP ET AL., UNIV. OF ALASKA ANCHORAGE INST. OF SOC. & ECON. RESEARCH, THE ECON. IMPORTANCE OF THE BRISTOL BAY SALMON INDUSTRY 1 (Apr. 2013), *available at* <http://fishermenforbristolbay.org/wp-content/uploads/2013/02/CFBB-ISER-FINAL-REPORT-5-10-2013.pdf>. This report was completed after publication of the second draft Watershed Assessment and should be reviewed and considered in the final Watershed Assessment.

In its revised Assessment, EPA clarifies the risks that large-scale mining poses to the Bristol Bay watershed, focusing on impacts to the region’s salmon and other fish populations, wildlife populations, and Alaska Native cultures.³ The agency underscores that even with no human or system failure (impossible in the long-term), a mine of any foreseeable size will reduce water flow in the region, directly eliminate up to 4,800 acres of wetlands, and dewater up to 90 miles of streams. With inevitable operational failures, EPA finds these risks would increase significantly, even catastrophically, in the event of a tailings dam failure.

Many of the comments responding to the first draft Assessment – ours included – highlighted EPA’s conservative underestimation of potential harm. We commend EPA for strengthening its assessment by addressing these critical risk factors, while nevertheless remaining consistently conservative in its projections of environmental impact. Notably, over half of the peer reviewers’ twelve “key” recommendations for revisions called on EPA to *add or supplement* sources of harm that it deemed insufficiently addressed in the first draft, or to explain the rationale for excluding potential impacts. Recommendations aimed at tempering risk projections – such as calling for analysis of a smaller mine scenario and of mitigation measures – have now been added to EPA’s second draft Assessment, and, in fact, they strengthen the case for 404(c) action.

EPA’s Assessment describes the adverse impacts that three different mine scenarios would have on the Bristol Bay environment. The scenarios are heavily based on mine details described in (1) Northern Dynasty Minerals’ (“NDM” or “Northern Dynasty”) “Preliminary Assessment of the Pebble Project, Southwest Alaska” (“Wardrop Report”),⁴ a 2011 document filed with the U.S. Securities and Exchange Commission, and (2) NDM’s 2006 “Surface Water Right Applications,” “Ground Water Right Applications,” and “Application for Certificate of Approval to Construct a Dam,” permit applications filed with the State of Alaska.⁵ The Assessment also considers the Pebble Limited Partnership’s (“PLP,” or “Pebble”) 2012 “Environmental Baseline Document” (“EBD”), which was intended to characterize the environmental studies conducted by PLP or its predecessors from 2004 to 2008.⁶ Pebble’s EBD has not yet undergone a thorough, independent peer review.

³ EPA, AN ASSESSMENT OF POTENTIAL MINING IMPACTS ON SALMON ECOSYSTEMS OF BRISTOL BAY, ALASKA (SECOND EXTERNAL REVIEW DRAFT) 910-R-12-004BA-C (2013) [hereinafter, “EPA ASSESSMENT”].

⁴ WARDROP, PRELIMINARY ASSESSMENT OF THE PEBBLE PROJECT: SW. ALASKA (Feb. 17, 2011), *available at*

http://www.northerndynastyminerals.com/i/pdf/ndm/Pebble_Project_Preliminary%20Assessment%20Technical%20Report_February%2017%202011.pdf [hereinafter “WARDROP, PRELIMINARY ASSESSMENT”].

⁵ PEBBLE PROJECT – WATER RIGHT APPLICATIONS, ALASKA DEP’T OF NATURAL RES., *available at* <http://dnr.alaska.gov/mlw/mining/largemine/pebble/water-right-apps/index.cfm>.

⁶ PEBBLE PROJECT: ENVTL. BASELINE DOCUMENT, <http://www.pebbleresearch.com/> (last visited June 25, 2013). Fully financed by PLP, the EBD purports to describe the existing physical and chemical (climate, water quality, trace elements), biological (wetlands, fish and aquatic invertebrates, wildlife, habitat), and social environments (land and water use, socio-economics, subsistence) within the Bristol Bay and Cook Inlet regions where development of the Pebble Mine is proposed. *Id.*

EPA’s analysis first considers “routine” operations and their “unavoidable” impacts – in other words, the environmental impacts that *will* take place if a mine is developed assuming that mine experiences no significant human or engineering failures during operation or in the following centuries. Though EPA cautions that this assumption is not realistic – and accidents and failures *always happen* in complex and long-lasting mining operations, even assuming flawless planning, engineering, operation, and maintenance – the Assessment anticipates unacceptable adverse effects on the Bristol Bay environment, which is the threshold for initiating 404(c) action. Even under routine operation, the agency documents unacceptable adverse effects on fish, streams, wetlands, and wildlife – including loss of streams, anadromous waters and wetlands, “toxic” levels of copper in the streams around the mine, reduced reproduction of salmonids, loss of population diversity, and the death of salmonids and invertebrates.⁷

EPA next reviews projected impacts from operational failures. The agency documents the “catastrophically damaging” impacts of a tailings dam failure to both fish and waters.⁸ Either standing alone or coupled with anticipated cumulative impacts, these devastating impacts unquestionably support a conclusion that 404(c) action is needed to prevent the foreseeable harm attendant to large-scale mining in the Bristol Bay watershed.

EPA’s Assessment paints a stark picture for Bristol Bay: far from being the “national treasure”⁹ and “significant resource of global conservation value”¹⁰ proclaimed by the Obama administration, the watershed would face certain dewatering, destruction, and pollution from large-scale mining like the Pebble Mine. Mining would risk not only the salmon – and both the commercial and sports fishing industries – but also the wildlife and people who depend on salmon to survive. Confronted with this documented risk of environmental destruction, EPA has the clear legal authority to take action under Section 404(c) of the Clean Water Act. That authority was recently upheld by the D.C. Court of Appeals, which reaffirmed EPA’s broad authority to prohibit, restrict, deny or withdraw areas for dredge and fill material under Section 404(c) “*whenever*” the agency finds unacceptable adverse effects.¹¹ If ever there were a case for using this power, it is the case of the Pebble Mine or any similar large-scale mine proposed to be located at the headwaters of Bristol Bay – particularly given Anglo American’s track record of polluting the environment and damaging the health of local communities. We discuss this record in Section IV below.

Advance 404(c) protection of Bristol Bay is supported by the Clean Water Act, and its regulations, prior interpretation and application, and consistent judicial precedent. Sound scientific analysis projects extreme and unacceptable impacts from mining in the region. EPA has the authority and the responsibility to prevent the certain devastation that

its Assessment describes. We therefore urge EPA to finalize its Watershed Assessment as promised in 2013 and immediately initiate action to prohibit large-scale mining – like the Pebble Mine – in the region.

II. THE REVISED ASSESSMENT AND RECENT COURT ACTION SUPPORT EPA AUTHORITY UNDER SECTION 404(C) TO PROTECT THE PEBBLE MINE AREA

EPA’s mandate under Section 404(c) of the Clean Water Act is to prohibit, deny, restrict, or withdraw dredge and fill projects that are reasonably likely to have an “unacceptable adverse effect on municipal water supplies, shellfish beds and fishery areas (including spawning and breeding areas), wildlife, or recreational areas.”¹² The Agency’s 404(c) authority to protect against such effects is both jurisdictionally expansive and substantively limited. On the one hand, EPA action is subject to no temporal limitation, as affirmed this April by the D.C. Circuit. EPA has the unequivocal right to act pursuant to Section 404(c) “*whenever*” failure to do so would result in unacceptable adverse environmental effects¹³ – before, during or after a permit application has been submitted.

On the other hand, EPA must find the requisite likelihood of “unacceptable adverse effect” to at least one of the prescribed areas of environmental impact. Despite the mining companies’ continued protestations to the contrary (“EPA has entirely ignored the economic and diversification benefits that mine development would bring to the local region, the State of Alaska and the United States”; “similarly conspicuous by its absence in [the Assessment] is any reference to unemployment and poverty data”¹⁴), 404(c) action is limited to an evaluation of impacts on the relevant *environmental resources only*. This includes: significant degradation of waters of the United States (40 C.F.R. § 230.10(c));¹⁵ secondary effects (40 C.F.R. § 230.11(h));¹⁶ and cumulative effects (40 C.F.R. § 230.11(g))¹⁷—and not, for example, copper’s role in “the United States’ economic and

national security.”¹⁸ Even Pebble has conceded this fact (in an instance when, true to form, they perceived some strategic advantage to contradicting an earlier position): “[the Clean Water Act] does not confer on EPA the authority to assess a project’s predicted adverse economic impact.”¹⁹

A. EPA Has Unequivocal Authority to Impose 404(c) Restriction “Whenever” it Deems Appropriate

Mining interests have consistently²⁰ taken the erroneous position that EPA cannot initiate 404(c) proceedings to protect Bristol Bay before a mine application has been submitted. This argument ignores the plain language of the regulation, *and it was flatly rejected by the D.C. Circuit last April.*

Upon review of EPA’s 404(c) veto, the court of appeals reversed a district court ruling that the agency lacked statutory authority to withdraw a disposal site specification of the Spruce No.1 Surface Mine permit four years after it was granted to Mingo Logan Coal.²¹ In making this determination, the court rejected the mining company’s argument that EPA’s authority under 404(c) is in any way temporally restricted. The 404(c) term “whenever,” the Court held, truly means *whenever*:

Using the conjunction “whenever,” the Congress made plain its intent to grant the Administrator authority to prohibit/deny/restrict/withdraw a specification at *any* time.

To find otherwise “would eliminate EPA’s express statutory right” and “thereby render 404(c)’s parenthetical ‘withdrawal’ language superfluous—a result to be avoided.”²²

Claims by PLP and NDM that EPA must wait to protect Bristol Bay until a mining application has been submitted are equally flawed. This would *both* render superfluous the “whenever” provision of the regulation *and* overtly contradict its plain language:

Reg. 38,519 (Oct. 16, 1987)); *see also* Final Determination Concerning the Jack Mayband Site Pursuant to Section 404(c) of the Clean Water Act, 50 Fed. Reg. 20,291 (May 15, 1985) (veto based in part on cumulative impacts to the area, including functional losses in the St. Helena Sound ecosystem, as described at 49 Fed. Reg. 30,112, 30,114 (July 26, 1984)); Water Pollution Control; Final Determination of the Assistant Administrator for External Affairs Concerning the Sweedens Swamp Site, 51 Fed. Reg. 22,977, 22,978 (June 24, 1986).

¹⁸ PEBBLE LIMITED PARTNERSHIP (CROWELL & MORING LLP) COMMENTS ON AN ASSESSMENT OF POTENTIAL MINING IMPACTS ON SALMON ECOSYSTEMS OF BRISTOL BAY, ALASKA, IN DOCKET NUMBER #EPA-HQ-ORD-2012-0276, at 24 (July 23, 2012), *available at* <http://www.northerndynastyminerals.com/i/pdf/ndm/attachment-3-of-8.pdf> [hereinafter “CROWELL & MORING”].

¹⁹ *Id.* at 12.

²⁰ *See, e.g.*, Press Release: Pebble Calls on the EPA to Abandon Flawed, Biased Approach (Apr. 26, 2013), *available at* <http://corporate.pebblepartnership.com/perch/resources/pebble-releaseepa-bbwa-1.pdf>; [hereinafter, “Apr. 26, 2013 PLP Press Release”]; CROWELL & MORING, *supra* note 18, at 3; NORTHERN DYNASTY 2012 COMMENTS, *supra* note 14, at 2-3.

²¹ *Mingo Logan Coal*, 714 F.3d at 609.

²² *Mingo Logan Coal*, 714 F.3d at 613–14.

The Administrator may [] prohibit the specification of a site under section 404(c) with regard to any existing *or potential* disposal site *before a permit application has been submitted* to or approved by the Corps or a state.”²³

The plain language of the regulation contradicts Pebble’s position that a “hypothetical” mine scenario is an improper basis for initiating 404(c) action. The regulation clearly contemplates 404(c) protection for “potential” disposal sites “before” submission of an application. Advanced restriction is just as viable as a 404(c) response to a permit application because both are based upon a predictive assessment from which “actual events will undoubtedly deviate.” Indeed, “[e]ven an environmental assessment of a proposed plan by a mining company would be an assessment of a scenario that undoubtedly would differ from the ultimate development.”²⁴

PLP and NDM further argue that an “expansive” interpretation of EPA’s authority under Section 404(c) is “unwarranted” because EPA’s role in Section 404 permitting is “secondary to that of the Army Corps of Engineers.”²⁵ This view not only misrepresents the longstanding construction of the regulations (“[w]hile Congress had faith in the Corps’ administrative experience, it recognized EPA as the ‘environmental conscience’ of the Clean Water Act”²⁶), but it too was refuted by the court of appeals in *Mingo Logan*:

[S]ection 404 vests the Corps, rather than EPA, with the authority to issue permits to discharge fill and dredged material into navigable waters and to specify the disposal sites therefor. ... Nonetheless, the Congress granted EPA a broad environmental ‘backstop’ authority over the Secretary’s discharge site selection in subsection 404(c)...²⁷

EPA’s 404(c) authority is not “confined to the permitting process under Section 404(a)” as the mining interests would have us believe, but rather, “[t]he Secretary’s authority to specify a disposal site is *expressly made subject* to subsection (c) of section 404.”²⁸

EPA’s position is not only legally sound, but also well-grounded in common sense. If PLP is entitled to file a permit application before EPA can act under 404(c), then other potential mining developers would presumably be similarly entitled, with the result that EPA would be required to take repeated actions under 404(c) to protect a single area. It makes far greater sense for EPA to proceed, as it has in this case, by

²³ 40 C.F.R. § 231.1(a) (2012) (emphasis added).

²⁴ EPA ASSESSMENT, *supra* note 3, at ES-27. See CHAMBERS, *supra* note 1, at Attachment B (hardrock mines frequently expanded beyond their initially permitted size).

²⁶ Denial or Restriction of Disposal Sites, *supra* note 12, at 58081.

²⁷ *Mingo Logan Coal*, 714 F.3d at 612 (internal quotations omitted).

²⁸ *Mingo Logan Coal*, 714 F.3d at 610 (internal quotations omitted) (emphasis added).

analyzing the potential effects of large-scale mining generally in an area of concern, based on scenarios that cover a range of potential mine design alternatives. Requiring the agency to wait for the filing of successive individual permit applications would result in a waste of resources, both for the agency and any interested parties.

And the resulting cloud of uncertainty would serve no one. Indeed, consideration of 404(c) action now is ultimately beneficial even to mine development interests like PLP, because it will protect it and other stakeholders with mining claims in the watershed from investing additional resources in a project manifestly unsuited to the pristine and ecologically rich Bristol Bay watershed. As EPA noted in 1979, the use of pre-application 404(c) protection “may well have some economic benefits that outweigh some of the costs,” because it takes place “before industry has made financial and other commitments.”²⁹ For mining interests that have emphasized the “nearly \$600 million” they have invested in the Pebble Project to date,³⁰ the *Mingo Logan* opinion – allowing for the withdrawal of a mining permit years after additional funds have been expended for research, development, and construction are complete – is a clear testament to the value of the advance 404(c) determination petitioned here. It would also address State concerns raised in the *Mingo Logan* case: namely, that delayed 404(c) action results in a “squandering” of State resources (i.e., reviewing permit applications and issuing permits and water quality certifications),³¹ which could otherwise have been avoided by an earlier determination.

B. The Science Supports 404(c) Action to Protect Bristol Bay

EPA has sufficiently established that mining in Bristol Bay would result in “unacceptable adverse effects” to fishery areas (including spawning and breeding areas), recreational areas, and wildlife, which is the statutory trigger under 404(c). In presenting its contrary view, however, PLP misstates the law by arguing that EPA, in order to exercise Section 404(c) authority with respect to any future Pebble mining project, must determine that the discharge of materials *will* have an unacceptable adverse impact,³² and that the regulation “plainly requires a showing of certainty.”³³ In fact, the threshold for action pursuant to Section 404(c) is a *reasonable likelihood* of unacceptable adverse effects:

[A]bsolute certainty is *not* required. Because 404(c) determinations are by their nature based on predictions of future impacts, what is required

²⁹ Denial or Restriction of Disposal Sites, *supra* note 12, at 58077 (“EPA feels that the statute clearly allows it to use 404(c) before an application is filed.”).

³⁰ Transcript of Interview by Monica Trauzzi with John Shively, CEO, Pebble Ltd. P’ship, on OnPoint (June 13, 2013), available at <http://www.eenews.net/tv/videos/1698/transcript>.

³² CROWELL & MORING, *supra* note 18, at 14.

³³ *Id.* at 16.

is a reasonable likelihood that unacceptable adverse effects will occur — not absolute certainty but more than mere guesswork.³⁴

In this case, there can be no reasonable doubt that this standard has been met. As EPA has explained, “regardless of design and operation standards, *any large-scale mine* in the Bristol Bay region would have a footprint that would affect aquatic resources.”³⁵ In other words, unacceptable adverse effects will occur from any large-scale mine developed in Bristol Bay regardless if the mine designs are based on 2006 State permit applications, 2011 SEC filings, or future permit applications. This is because Bristol Bay is home to the largest sockeye salmon fishery in the world, supporting 46% of the average global abundance of wild sockeye salmon. Between 1990 and 2009, the average annual inshore run of sockeye salmon in Bristol Bay was approximately 37.5 million fish. Of the sub-watersheds in the Nushagak and Kvichak River watersheds, 63% are documented to contain at least one species of spawning or rearing salmon within their boundaries, and 12% are documented to contain all five species.³⁶

Any large-scale mining in the Bristol Bay region – regardless of the exact mine plan – “would necessarily involve the destruction of streams and wetlands through excavation and filling associated with the mine pit, waste rock piles, tailings impoundments, borrow pits, and the transportation corridor.”³⁷ Downstream water flow reduction would irreparably degrade salmon populations and fisheries, and damage one of the very keys to salmon health and volume in this area — their biodiversity. The required new access road would cause population fragmentation, exposure to sediment, and decreased groundwater-surface water connectivity. Furthermore, salmon prevalence supports Bristol Bay’s ecosystem strength as a whole, and degraded salmon populations would impair the region’s wildlife. Alaska Natives would suffer health and cultural harm from mining because for centuries their way of life has depended on salmon for subsistence, as well as for cultural, social, and spiritual identity.³⁸

Specifically, EPA breaks its analysis down to “routine” (failure-free) mining operations with “unavoidable” adverse effects, and those resulting from failures – both day-to-day and severe, including human error, mechanical failure, accidents, and other unplanned events. Unavoidable effects are *expected* to occur even if the mine is flawlessly built, operated, and closed. The Assessment reveals that these alone are sufficient to trigger 404(c). When potential failures are added to this analysis, impacts are even more extreme, and projections of adverse effects are dire. Mining impacts are fundamentally pessimistic because over the extreme long-term, even those failures with low statistical probability become “likely.”³⁹ Their low probability derives from a very low rate of occurrence, but over the centuries-long existence of a mine, some sort of failure is expected.

³⁴ Denial or Restriction of Disposal Sites, *supra* note 12, at 58078 (emphasis added).

³⁵ EPA ASSESSMENT, *supra* note 3, at 6-3 (emphasis added).

³⁶ *Id.* at 5-11.

³⁷ *Id.* at 6-37.

³⁸ *Id.* at ES-24 to ES-25.

³⁹ *Id.* at 14-17.

The unavoidable impacts of three “perfectly performed” mine scenarios with no accidents, leaks or failures, in which 0.25, 2.0, and 6.5 billion tons of ore are extracted over the course of 20, 25, and 78 years, respectively, include:

- Loss of 24, 56, or 90 miles of streams, constituting 4%, 9%, and 14% of total stream length within the mine footprint;
- Loss of 5, 15, or 22 miles of documented anadromous waters (2%, 7%, and 11% of total anadromous fish stream length), known to support spawning and rearing habitat for coho, Chinook, and sockeye salmon and Dolly Varden;
- Loss of 11.5 to 42 miles of headwater streams supporting habitat for non-anadromous fish species;
- Altered groundwater-surface water hydrology between the main channel and off-channel habitats, which are critical to juvenile salmonids, nutrient processing, and export rates of resources and materials for aquatic ecosystems;
- Loss or substantial change of riparian floodplain wetland habitat;
- Streamflow reductions causing adverse effects on habitat in 9.3, 16, and 34 miles of streams;
- Erosion of population diversity essential to the stability of the overall Bristol Bay salmon fishery;⁴⁰
- Leakage sufficient to cause toxic levels of copper in 38 and 51 miles of stream under the Pebble 2.0 and 6.5 scenarios, respectively.⁴¹

Because EPA evaluated only the components of a mine that have the potential to adversely affect aquatic resources regulated under the Clean Water Act, the cumulative footprint of a large-scale mine at the Pebble deposit would likely be much larger than the described scenarios. For example, by adding mining and processing facilities, drainage management structures, other storage and disposal facilities, and other operational infrastructure – as described in NDM’s Wardrop Report – the footprint of Pebble 2.0 would increase from 9.7 to 36 square miles, the mine site would contain more than 12 miles of main roads (as well as numerous pit and access roads), and the net power generation would exceed by more than 100 times the current maximum electrical load of the largest population center in the Bristol Bay watershed.⁴²

Clearly, even these “unavoidable” effects would alter Bristol Bay completely and irreparably. Yet, a mine without failures is simply not a realistic possibility. Failures “always happen in complex and long-lasting operations,”⁴³ EPA explains, “even if their magnitude is ‘uncertain.’”⁴⁴ And once failures are incorporated into the analysis, long-term environmental damage could be “catastrophically damaging to fisheries.”⁴⁵ EPA’s

⁴⁴ DAVID A. ATKINS ET AL., AN ASSESSMENT OF POTENTIAL MINING IMPACTS ON SALMON ECOSYSTEMS OF BRISTOL BAY, ALASKA 16 (Sept. 17, 2012), *available at* <http://www2.epa.gov/bristolbay/peer-review-process> [hereinafter, “PEER REVIEW”].

⁴⁵ EPA ASSESSMENT, *supra* note 3, at 13-30.

conclusions regarding impacts from failures of a tailings dam; product concentrate, return water, or diesel pipelines; roads and culverts; or water collection and treatment include:

- Loss of more than 18 miles of salmonid stream and associated wetlands for years to decades (a highly conservative estimate of what would more likely extend well over 90-185 miles in the Bristol Bay Watershed);⁴⁶
- Acute and chronic toxic exposure to fish and invertebrates;
- Impeded fish passage in 11 to 21 salmonid streams;⁴⁷
- Wastewater treatment plant releases ranging from short-term and innocuous to long-term and highly toxic to fish and invertebrates.⁴⁸

An additional and acute risk of mining in Bristol Bay stems from the region's diverse hydrologic landscapes, which "shapes the quantity, quality, diversity, and distribution of aquatic habitats throughout the watershed," and creates a freshwater system that supports multiple critical salmon life stages.⁴⁹ As described more fully in Section III.B.4 below, mining would alter groundwater-surface water hydrology, nutrient processing, and export rates of resources and materials for aquatic ecosystems downstream. The "inherent complexity" of the region's salmon-supporting hydrology means that hydrological models used to estimate exposures are "inevitably simplifications."⁵⁰ It is therefore extremely difficult to identify and control the potential range of impacts from mining,⁵¹ creating "one of the greatest sources of uncertainty for the water quality risks."⁵²

Interactions between salmon and other wildlife species are "complex and reciprocal,"⁵³ and reduction in wildlife would be expected from the mine scenario footprint and from routine operations under each scenario. The highly productive Pacific salmon runs also directly contribute to the large wildlife populations in the region. Salmon are a "cornerstone" species,⁵⁴ with deep importance to the greater ecosystem. They affect ecosystem productivity and regional biodiversity through nutrient transportation.⁵⁵ A wide number of animals feed on salmon, including brown bears, bald eagles, other land birds and wolves. These animals would suffer direct effects by a reduction in salmon abundance. The effects of reduced salmonid production on wildlife would be complex, difficult to quantify, and may not be linearly proportional. The loss of salmon – and brown bears as a result – would result in "significant changes in the productivity, diversity and physical structure of their communities far beyond just their

⁵⁵ EPA ASSESSMENT, *supra* note 3, at 5-27 to 5-28.

‘food chain’ interactions.”⁵⁶

Alaska Natives and Bristol Bay residents in the watershed also depend – and have for generations – on salmon for their subsistence. Alaska Natives are “particularly vulnerable” to any changes in the quantity or quality of salmon resources,⁵⁷ and reduced salmon stocks would seriously threaten their health, way of life, and the survival of their communities. Subsistence-based living is vital to Alaska Native identity, and it plays a central economic, social, and cultural role. Any change in salmon resources would likely have detrimental adverse effects on human health, spiritual well-being, the social support system of food sharing, cultural continuity, and mental health.⁵⁸

Finally, as EPA accurately notes, the region “takes on even greater significance when one considers the condition of Pacific salmon populations throughout their native geographic distributions.” Pacific salmon are gone from 40% of their historical breeding ranges in the western United States. Where populations remain, their numbers tend to be significantly impaired or dominated by hatchery fish. This status of Pacific salmon throughout the United States underscores the “value of the Bristol Bay watershed as a salmon sanctuary or refuge,” and highlights the Bristol Bay watershed as a “significant resource of global conservation value.”⁵⁹ Allowing its degradation should be out of the question.

III. EPA SOUGHT EXTENSIVE PUBLIC INPUT AND REVISED ITS ASSESSMENT TO ADDRESS THE CONCERNS OF SUPPORTERS AND CRITICS ALIKE

EPA should be applauded for releasing a revised Assessment that so thoroughly addresses the questions raised by the peer review panel, stakeholders, and members of the public. Throughout this process, EPA has elicited extensive input, provided open access and communication, and sought independent review, and the result is an Assessment that is analytically rigorous and scientifically sound.

A. The Assessment Process Has Been Open to Extensive Public Input

EPA has consulted relevant stakeholders and received extensive public input and evaluation at every stage of development of the Watershed Assessment, including extending the current comment period by an additional 30 days. Predictably, Pebble argues otherwise, protesting that EPA fails a “key component of the need for transparency,” of “active, meaningful engagement with interested stakeholders.”⁶⁰ It claims that PLP has “largely been excluded from the Assessment’s planning,

⁵⁶ *Id.* at 14-12.

⁵⁷ *Id.*

⁵⁸ *Id.*

⁵⁹ *Id.* at 5-27.

⁶⁰ CROWELL & MORING, *supra* note 18, at 6.

development, risk characterization, and analysis.”⁶¹ These accusations are only a smoke screen for PLP’s own opportunism and strategic withholding of information. EPA’s transparency, and the depth of its public engagement, are indisputable.

Prior to release of the first draft Assessment, EPA held meetings and telephone calls with thousands of stakeholders, and engaged in tribal consultation and public meetings. After releasing the draft, EPA held eight noticed public hearings,⁶² and a public comment period, during which it received over 233,000 public comment letters. *Of these, over 90% expressed support for the Assessment and/or EPA action.*⁶³ The Agency then tasked an independent contractor to assemble objectively a peer-review panel based on public nomination and to conduct an external peer review of the Assessment. This process resulted in “a documented, independent, and critical review of the draft assessment” with the purpose of identifying any “problems, errors, or necessary improvements to the report.”⁶⁴ Finally, EPA incorporated the public and peer input into its revised draft Assessment, *also now subject to an additional public comment and second peer review.*⁶⁵ This certainly goes above and beyond EPA Guideline requirements, which contain no obligation (or mention) of a second review or comment period.⁶⁶

It was PLP – invited to participate from the start – that refused to disclose the extensive environmental data that had been in the company’s possession for *years*. In February 2011, EPA announced its plans to prepare the Watershed Assessment, soliciting input from the scientific community, tribes, and local and state agencies, as well as the public and industry.⁶⁷ At that time, EPA announced its plan to complete the review within six to nine months, setting a clear timeline for stakeholders to provide relevant materials

⁶¹ *Id.* at 6. Similarly, NDM accuses EPA of “improperly control[ing] the Peer Review Panel’s evaluation and input” and “restrict[ing] public access to the Panel.” Letter from Ron Thiessen, CEO, N. Dynasty Minerals Ltd., to Bob Perciasepe, Acting Admin., EPA (May 30, 2013), *available at* http://www.northerndynastyminerals.com/i/pdf/ndm/bbwa/NDM_LetterToEPA_May2013.pdf. Yet as EPA notes, the peer review was an opportunity for extensive public involvement. The public was invited to nominate potential peer reviewers, and to submit comments on the charge questions to be given to peer reviewers. The public was also invited to participate in 2 of the 3 days of peer review meetings. EPA ASSESSMENT, *supra* note 3, at 1-6. Peer reviewers heard testimony from around 100 members of the public, and received a summary of the 220,000 comments submitted to EPA. BRISTOL BAY ECOSYSTEMS & COMM’NS, EPA REGION 10, at ii, a-2, *available at* <http://www2.epa.gov/bristolbay/peer-review-process> (last visited June 26, 2013). This high level of public engagement is commendable, as, according to EPA, involving the public in the peer review process is discretionary, to be undertaken when “feasible and appropriate.” EPA, PEER REVIEW HANDBOOK EPA/100/B-06/002, at 59 (3rd ed. 2006), *available at* http://www.epa.gov/peerreview/pdfs/peer_review_handbook_2012.pdf.

for review.⁶⁸ Although research for PLP’s “Environmental Baseline Document” was effectively completed by 2008,⁶⁹ Pebble inexplicably withheld the 27,000-page EBD until February 2012,⁷⁰ a year after EPA’s call for materials and only three months before the draft Watershed Assessment was finalized. After holding back the requested information, Pebble now complains that its data were “largely ignore[d]” by the agency. Pebble also suggests its own data “mitigates against a need for EPA to gather additional data.”⁷¹ However these data were fully financed by PLP and – unlike the Watershed Assessment itself – have not completed independent peer review. Notwithstanding the disingenuous nature of PLP’s grievances, EPA has been responsive and incorporated EBD data into its revised Assessment.⁷²

B. EPA Enhanced the Assessment in Order to Address Comments by the Public and Peer-Review Panel

EPA has done an extraordinary job of addressing the range of questions raised during the public comment and peer-review process. In particular, it (1) expanded the range of mine scenarios, (2) added a review of potential mitigation measures, (3) incorporated the risks and unknowns attendant to projected climate change, (4) strengthened its analysis of the complex and interconnected hydrology of the region, (5) added “day-to-day” operational risks, and (6) enhanced its analysis of cumulative impacts. The result is a well-documented scientific analysis of the myriad unacceptable adverse effects that would result from mining. The analysis ultimately supports 404(c) protection.

1. The Assessment Includes a Broader Range of Mine Scenarios

EPA directly responds to the peer-review recommendation that it “[c]onsider adopting a broader range of mine scenarios, especially smaller size mines.”⁷³ The Assessment now includes Pebble 2.0 (1.8 billion metric tons of ore) and Pebble 6.5 (5.9 billion metric tons of ore), and adds a third and smaller Pebble 0.25 (0.23 billion metric tons of ore) even though a smaller mine is not economically viable in the region.⁷⁴ EPA describes each of the three scenarios as “realistic, plausible descriptions of potential mine development alternatives, consistent with current engineering practice and precedent.”⁷⁵ However, only the larger two mine sizes are likely to be pursued at the Pebble deposit. They are in fact already being contemplated by PLP.⁷⁶

⁷⁴ EPA ASSESSMENT, *supra* note 3, at 6-1.

⁷⁵ *Id.*

⁷⁶ See WARDROP, PRELIMINARY ASSESSMENT, *supra* note 4, at 4–5.

As EPA explains, Pebble 2.0 and Pebble 6.5 reflect projects “which are described in [the Wardrop Report]” as “economically viable, technically feasible and permissible” development.⁷⁷ Because the Pebble deposits are low-grade deposits (the metal-to-ore ratio is low), mining in the area will only be economical if conducted over a large area, producing a large amount of waste. PLP initially proposed extracting 2.5 billion tons of ore from the Pebble deposits, which would require two tailings ponds with five total dams,⁷⁸ but later announced that the deposit contains nearly 11 billion tons of ore.⁷⁹ Even if a mine on the lower end of this range is *first* approved, multiple expansion and permitting cycles are common and foreseeable for hardrock mine sites.⁸⁰ If fully mined, this would represent the largest mine of its type in North America.

Though the “development of conceptual models is a key component of the problem formulation stage of an ecological risk assessment,”⁸¹ the Assessment represents more than mere concept. These mine scenarios are not hypothetical, but rather “draw on plans developed for Northern Dynasty Minerals, consultation with experts, and baseline data collected by the Pebble Limited Partnership to characterize the likely mine site, mining activities, and surrounding environment.”⁸² EPA’s placement of the mine components described in the scenarios is also based on information either from the Wardrop Report, or where, in EPA’s experience, modern mining practice suggests a component would be placed.⁸³ In each case, these layouts include the mine footprint, mine pit, waste rock piles, and TSFs, “represent[ing] one possible configuration for the mine.” While other configurations are possible, they “would be expected to have impacts of similar types and magnitudes.”⁸⁴

2. Mitigation Measures Are Insufficient to Avoid Unacceptable Adverse Effects, Even Including “Best Practices”

In response to comments from both the peer-review panel and the mining companies,⁸⁵ EPA’s second draft Assessment includes detailed discussion of potential mitigation measures, including modern conventional mitigation practices as reflected in

⁷⁷ EPA ASSESSMENT, *supra* note 3, at 6-19.

⁸² *Id.* at ES-10.

⁸³ For example, TSFs are placed in the locations described in the Wardrop Report and where topography provides an efficient location to store a large volume of tailings; waste rock is placed around the pit to minimize the cost of hauling millions to billions of tons of material; and the transportation system is located within the corridor described in the Wardrop Report. *Id.* at 6-2.

⁸⁴ *Id.* at 6-20.

⁸⁵ PEER REVIEW, *supra* note 44, at iii; N. DYNASTY 2012 COMMENTS, *supra* note 14, at 15–17; Apr. 26, 2013 PLP Press Release, *supra* note 20.

NDM’s published plan for the Pebble deposit, plus practices suggested in the mining literature and consultations with experts.⁸⁶ Examination of the mitigation methods outlined by NDM dispels any illusion that large-scale mining could ever coexist with Bristol Bay salmon ecosystems. Mitigation options fail to adequately address flow reductions and stream habitat losses, impacts from tailings storage and the transportation pipeline and corridor, or losses to Alaska Native subsistence use of the salmon.⁸⁷

A number of factors render successful mitigation of large-scale mining in Bristol Bay unlikely, even assuming “best practices.” First, unlike most other areas supporting Pacific salmon populations, this watershed is undisturbed by significant human development.⁸⁸ Second, Bristol Bay has ecological importance well beyond its boundaries as a “significant resource of global conservation value,”⁸⁹ which once lost simply cannot be recovered. Next, physical and hydrologic complexities render predictions of the *full* impacts from mining (and what must therefore be mitigated) extremely problematic. Finally, the risks – and potential consequences of those risks – increase over time, particularly with the additional impacts of climate change. Adverse impact avoidance would require long-term monitoring and maintenance from future generations of mine operators, who will instead be motivated by the economic realities of the moment, assuming these mining entities actually endure through the years—an unlikely proposition over the entire life of the mine.

a) *Unavoidable Habitat and Flow Losses Cannot be Mitigated*

Where impacts from a dredge and fill project are unavoidable, such as the habitat and flow losses resulting directly from the mine footprint and transportation corridor described in the Assessment, the Clean Water Act requires compensatory mitigation to replace the loss of wetland and aquatic resource functions in the watershed. Compensatory mitigation refers to the “restoration, establishment, enhancement, or in certain circumstances preservation of wetlands, streams or other aquatic resources for the

⁸⁶ EPA ASSESSMENT, *supra* note 3, at ES-26.

⁸⁷ Nor is remediation a viable option:

Although remediation would be considered if spills contaminated streams, features of the Pebble deposit area would make remediation difficult. Pipeline crossings of streams would be near Iliamna Lake, so the time available to block or collect spilled material would be short. Spilled return water and the aqueous phase of the product concentrate slurry would be unrecoverable. The product concentrate itself would resemble fine sand, and mean velocities in many receiving streams would be sufficient to suspend and transport it. Hence, concentrate spilled or washed into streams could be recovered only where it collected in low-velocity locations. Diesel spills would dissolve, vaporize, and flow as a slick to Iliamna Lake. Booms and absorbents are not very effective in moderate-to high-velocity streams. Spilled tailings from a dam failure would flow into streams, rivers, and floodplains that are in roadless areas and not large enough to float a barge-mounted dredge. Recovery, transport, and disposal of hundreds of millions of metric tons of tailings under those conditions would be extremely difficult and would result in additional environmental damage.

Id. at ES-26.

⁸⁸ *Id.* at 3-35.

⁸⁹ *Id.* at 5-27.

purpose of offsetting unavoidable adverse impacts,⁹⁰ and is an option once all opportunities for aquatic resource impact avoidance and minimization have been exhausted.⁹¹

To fulfill this requirement, mitigation must be commensurate with the amount and type of impact. Compensatory mitigation should generally occur within the same watershed as the impact site and in a location where it is most likely successfully to replace lost functions and services.⁹² It must be, to the extent practicable, “sufficient to replace lost aquatic resource functions.”⁹³ Where there is a “lack of appropriate and practicable compensatory mitigation options” – as is the case here – discharge of dredge or fill is not permissible.⁹⁴

Because the Bristol Bay region is currently in a “pristine condition,”⁹⁵ compensation within the watershed is unachievable – there is currently no development to mitigate. Further, serious questions exist as to whether compensation measures could address the impacts of the type and magnitude likely to result from mining.⁹⁶ As explained in detail in the Assessment, each method for compensatory mitigation, including mitigation bank credits, in-lieu fee program credits, and opportunities within the North Fork Koktuli, South Fork Koktuli, and Upper Talarik Creek Watersheds (e.g., beaver dam removal, flow management, spawning channel construction, preservation, off-site and out-of-kind opportunities, old mine site remediation, road removal, road stream crossing retrofits, hatchery construction, fish stocking, and commercial fishery harvest reductions), would face “significant challenges” in the Bristol Bay environment.⁹⁷ Northern Dynasty’s recent claims that it would be possible to counterbalance large-scale mining impacts by improving the quality and complexity of off-channel habitat and increasing connectivity within the watershed are scientifically unfounded.⁹⁸

b) *Impacts from Mine Operations and Maintenance Cannot be Adequately Mitigated*

Leakage under the Pebble 2.0 and Pebble 6.5 scenarios would be sufficient to cause toxic levels of copper and, to a lesser extent, other metals in the streams draining the mine scenario footprints. Foreseeable impacts include death or inhibited reproduction of aquatic invertebrates in 38 to 51 miles of stream, salmonid avoidance of 18 to 35 miles of streams, and death and reduced reproduction of salmonids in 2.4 to 7.5 miles of

streams.⁹⁹ A mine design based on conventional practices could be sufficient for a typical porphyry copper mine equivalent to Pebble 0.25, but not for the more likely Pebble 2.0 and 6.5 mine sizes. Even additional “best practice” mitigation measures, such as lining waste rock piles or reconfiguring the piles,¹⁰⁰ raise questions of efficacy. Liners create stability risk, and liner material breakdown and punctures by equipment or rocks can limit their effective life. The cost is also potentially prohibitive.¹⁰¹ It is also reasonable to ask how a “best practice” can be designed when longer-term behavior of the materials and their distribution within a waste rock pile is not fully understood.¹⁰²

Effective mitigation is certainly unlikely in a region for which a Pebble 6.5 leachate barrier or collection system would require *more than 99% effectiveness* to avoid exceeding the copper criteria.¹⁰³ For example, even where a waste rock pile is constructed based on sound studies of current risk, the properties of the pile may change over time and breaches may occur. Freeze/thaw cycling in colder climates may cause cracks, channeling, and exposure of surfaces below the cover, which could result in accelerated weathering and leaching of materials.¹⁰⁴ Post-closure, the volume of water requiring treatment would range from 10 million m³/yr for Pebble 0.25 to over 50 million m³/yr for Pebble 6.5.¹⁰⁵ There is simply *no precedent* for the long-term management of water quality and quantity on this scale at an inactive mine¹⁰⁶— let alone at a rate of 99% effectiveness.

Northern Dynasty erroneously claims that treated water could be returned to the watershed without compromising the complex groundwater hydrology of the region. The methods they present for doing so are unproven and would be experimental, and their efficacy is not supported by scientific documentation.¹⁰⁷ Furthermore, NDM’s proposals fail to recognize “basic salmon life history”: salmon imprint on natal stream chemistry, enabling them to return and spawn in the streams to which they are adapted. Altering the water chemistry of area streams could cause salmon straying, failure to spawn, and death.¹⁰⁸

With respect to the area proposed for a road and pipeline corridor, “special circumstances”¹⁰⁹ render “highly uncertain” the effectiveness of even “state of the art”

⁹⁹ EPA ASSESSMENT, *supra* note 3, at 14-3.

¹⁰⁷ CTR. FOR SCI. IN PUB. PARTICIPATION, *supra* note 98, at 6.

¹⁰⁸ *Id.* at 8, 11-12.

¹⁰⁹ These “special circumstances” include the following constraints on mitigation:

- 1) Subarctic extreme temperatures and frozen soil conditions could complicate planning for remediation, with outcomes uncertain as a result of variable conditions and spill material characteristics.

best-practice mitigation measures.¹¹⁰ Environmental mitigation methods identified in the Wardrop Report suffer from being “mutually exclusive or offsetting,” “potentially superseded or limited by engineering, operational, maintenance, or fiscal concerns,” or “likely to be ineffective given the hydrogeomorphology, subarctic climate and hydrogeologic conditions, seismicity, and pristine condition and inherent sensitivity of the environment in Bristol Bay watershed”.¹¹¹

For instance, limiting the area disturbed by the transportation corridor creates risk from “stacking” the road and pipelines closely together.¹¹² When minimizing stream crossings, the two most potentially effective mitigation measures “stand in opposition to each other,” because the “tortuous” nature of a route with the fewest stream crossings would undermine the intent of minimizing area of disturbance.¹¹³ And burial or boring of pipelines underground can disrupt subsurface hydrology.¹¹⁴ As these examples reveal, “there is no ‘free lunch’ when it comes to mitigating the environmental impacts of a new road in a previously roadless landscape.”¹¹⁵

c) Direct and Indirect Loss to Alaska Native Subsistence Uses Cannot be Mitigated

Impacts to the salmon subsistence resource – permanent and in perpetuity – resulting from any of the mine scenarios will in turn represent a loss to traditional Alaska Native communities. “The importance of salmon to Alaska Native cultures is well documented.”¹¹⁶ Because Alaska Natives have “significant ties to specific land and water resources that have evolved over thousands of years, it would not be possible to replace the value of lost subsistence use areas elsewhere, or to relocate residents and their cultures, making compensatory mitigation infeasible.”¹¹⁷ These adverse effects are unacceptable under Section 404(c).

2) Subarctic climatic conditions limit the lushness and rapidity of vegetation growth or re-growth following ground disturbance, reducing the effectiveness of vegetated areas as sediment and nutrient filtration buffers.

3) Widespread and extensive areas of near-surface groundwater and seasonally or permanently saturated soils limit potential for absorption or trapping of road runoff, and increase likelihood of its delivery to surface waters.

4) Likelihood of ice flows and drives during thaws that can make water crossing structures problematic locations for jams and plugging.

5) Seismically active geology; even a small increment of ground deformation can easily disturb engineered structures and alter patterns of surface and subsurface drainage in ways that render engineered mitigations inoperative or harmful.

6) Remote locations that are not frequented by human users, hence mitigation failures and accidents may not be detected until substantial harm to waters has occurred.

¹¹⁴ *Id.* at app. G, 31–32.

¹¹⁵ EPA ASSESSMENT, *supra* note 3, at app. G, 34.

¹¹⁶ *Id.* at 12-6.

¹¹⁷ *Id.* at 12-15.

With mitigation infeasible, the ability of Alaska Natives to adapt to an impaired salmon and subsistence landscape is important, but unknown. Even assuming that adaptation is possible, it would come with significant losses to both a centuries-old traditional culture and to the regional environment. Traditional languages, patterns of behavior, economic activities, skills and capital improvements that would no longer be relevant may be lost, and use of non-renewable resources within the new development would augment the induced mining effects described above.¹¹⁸

3. Expected Future Climate Change Increases the Long-Term Risk of Unacceptable Adverse Effects

The physical environment in Alaska is projected to transform dramatically due to enhanced variability of climate conditions in the coming decades and centuries. For this reason, and particularly because a mine in Bristol Bay would require post-closure management in perpetuity, the peer-review panel strongly urged EPA to more fully consider the broad range of impacts from climate change.¹¹⁹ EPA has done so and documents in its revised Assessment how severely climate change could impact and undermine even the “best” mine site structures, operations and maintenance, and, in turn, the salmon-dependent ecosystems as well as the communities and wildlife that rely on these ecosystems.

Projected increases in temperature and precipitation from climate change in the Bristol Bay region are expected to alter substantially the physical environment. Across the Bristol Bay watershed, average temperature is projected to increase by approximately 4°C by the end of the century, with winter temperature increasing the most. Precipitation is expected to rise by 30% across the watershed, for a total increase of approximately 250 mm annually. Annual water surpluses are expected to increase 144 mm and 165 mm in the Nushagak and Kvichak River watersheds, respectively, in the Bristol Bay watershed.¹²⁰

Climate change will likely result in modified snowpack and timing of snowmelt, a greater chance for rain-on-snow events, and an increase in flooding.¹²¹ On their own, these climate alterations will impact salmon fishery and populations. Without the additional stress of development impacts, however, salmon may adapt, as they have to the already higher Alaskan temperatures.¹²² If climate change is instead layered onto an ecosystem already bearing the burden of (even the smallest) mine scenario, such resilience is doubtful. For example, asynchrony in spawning timing helps buffer Bristol Bay salmon populations from climatic events. The decline in physical and hydrological complexity that would result from mining, described in more detail in Section III.B.4 below, would therefore reduce salmon resistance to the effects of climate change¹²³ and further compound the mine’s unacceptable adverse effects.

¹¹⁸ *Id.*

¹¹⁹ PEER REVIEW, *supra* note 44, at 8.

¹²⁰ EPA ASSESSMENT, *supra* note 3, at 3-39.

¹²¹ *Id.* at 14-15.

¹²² *Id.* at 3-36.

¹²³ *Id.* at 8-64.

In addition, climate change may make the design of a compliant and safe facility that follows operational best practices extremely difficult.¹²⁴ The uncertainties already inherent in developing a mine in a *known* climate have the potential to be dramatically magnified by changing climate conditions. Risk-inducing uncertainty includes: (1) the stability of tailings impoundments and other facilities in response to more variable and intense climate events; (2) modeling potential flows for transport of contaminants away from the mining site during both catastrophic and non-catastrophic releases; and (3) assessing the additional stress a more variable and intense hydrologic system will have on ecosystems already stressed by normal operational degradation of water quality and quantity.¹²⁵ In the face of such uncertainty, development of a mine in Bristol Bay capable of withstanding the long-term stability challenges of a changing environment is, at best, unlikely.

4. The Hydrologic Nature of the Watershed Would Magnify the Unacceptable Adverse Effects and Unpredictable Impacts of Mining

Bristol Bay is unique, not for having developed into a deeply interconnected ecosystem, but rather for the exceptional fact that this hydrology is still fully functional and has not been disturbed by human activity. Overall physical habitat complexity in the Bristol Bay watershed is higher than in many other systems supporting sockeye salmon populations. For example, of 1,509 North Pacific Rim watersheds, the Kvichak River ranks third in physical habitat complexity.¹²⁶ Closely tied to this physical complexity is the biological interconnectedness of Bristol Bay; salmon life-history variability fortifies ecological productivity and stability for the region as a whole. These facts inspired requests by the public¹²⁷ and the peer-review panel for EPA to “[s]trengthen the assessment with additional information to characterize the interconnectedness of groundwater and surface water and its importance to fish habitat in the watersheds.”¹²⁸ The requested analysis now forms part of EPA’s revised Assessment and dramatically strengthens the call for 404(c) action.

System-wide connectivity and biological complexity provide *the foundation* for the exceptional quality and resilience of the Bristol Bay fish populations. As EPA explains, variations in temperature and streamflow associated with seasonality and groundwater-surface water interactions create a “habitat mosaic” and “biological portfolio effect” that stabilize salmon productivity across the watershed as a whole and in response to changes in environmental conditions.¹²⁹ Thus, the watershed’s sockeye salmon “population” is actually “a combination of hundreds of genetically distinct

¹²⁹ EPA ASSESSMENT, *supra* note 3, at 5-25.

populations, each adapted to specific, localized environmental conditions.”¹³⁰ The loss of even a small stock within an entire watershed’s salmon population can therefore cause more than concomitant effects, due to associated decreases in biological complexity of the population’s stock complex.¹³¹

This inherent intricacy of groundwater-surface water exchanges makes regulating or controlling such interactions during large-scale landscape development extraordinarily difficult.¹³² These complex interactions simply cannot be boiled down to a one-to-one calculation. NDM asks EPA and the public to believe that a mine occupying only a small percentage of the Nushagak-Mulchatna and Kvichak drainages “could not meaningfully impact ecological resources” over the “broad” Bristol Bay area.¹³³ As noted by the peer-review panel, however, the relationship between habitat and salmon production is “non-linear.” Even “5% of the habitat could be critical and thus responsible for 20% or more of salmon recruitment.”¹³⁴

Absent system-wide biological complexity, annual variability in the size of Bristol Bay’s sockeye salmon runs would be expected to *more than double* and more frequent fishery closures would be expected.¹³⁵ The streams that would be lost under any of the three mining footprint sizes include those that directly provide habitat for salmonids, as well as those that may not contain salmonids at all times of year but provide important sources of water, macroinvertebrates, and other materials.¹³⁶ As discussed above, NDM’s recent submission to EPA outlining mitigation options is mere fantasy. Because predicting and regulating flows to maintain groundwater-surface water exchange would be “particularly challenging,”¹³⁷ attempts to avoid harm or remediate interconnectivity are likely to be futile – and the unacceptable adverse effects are likely to be severe.

5. “Day-to-Day” Water Treatment and Transportation Corridor Operations Would Cause Unacceptable Adverse Effects in Bristol Bay

The peer review panel noted that the risks associated with potential spills from “day-to-day” operations – such as risks from water treatment, pipeline and road-culvert failures – deserved more attention in the Assessment.¹³⁸ In response, EPA developed a systematic model of potential surface and groundwater contamination from releases, cumulative effects and management problems. The model assumes best management practices and applies both during day-to-day operations and after the mine’s closure.

¹³⁸ PEER REVIEW, *supra* note 44, at iv.

a) *Leachate Escape and Treatment Failure are Foreseeable*

EPA has added a new chapter to its second draft Assessment on Water Collection, Treatment, and Discharge. In response to peer-review recommendations that EPA emphasize “the leaching potential of acid-generating and non-acid generating waste rock and tailings, given the low buffering capacity and mineral content in the streams and wetlands that could receive runoff and treated water from the proposed mine,”¹³⁹ the agency comprehensively describes the potential sources of water contaminants, as well as the potential routes and magnitudes of exposure to contaminated water. Exposure-response relationships used to screen leachate constituents are considered in detail, as is the toxicology of the major contaminant of concern, copper.¹⁴⁰ Consistent with the structure of the Assessment as a whole, EPA separates its analysis of adverse effects that would result from routine operations, from those produced by failures. All are unacceptable under 404(c) standards.¹⁴¹

The Assessment reveals that even if the wastewater treatment system operates *perfectly* for the rest of time – an impossible proposition – water quality would suffer unacceptable adverse effects from copper and other metals that leach from tailings and waste rock, escape capture, and move to shallow groundwater and surface water. These adverse effects under routine operations include:

- Toxic effects from acute and chronic copper exceedances on aquatic invertebrates in 9.3, 39, and 52 miles of streams in the Pebble 0.25, 2.0, and 6.5 scenarios, respectively;¹⁴²
- Copper concentrations sufficient to cause fish avoidance of 18 (Pebble 2.0) and 35 miles (Pebble 6.5) of streams;¹⁴³
- Copper concentrations sufficient to kill fish in 2.4 (Pebble 2.0) and 7.5 miles (Pebble 6.5) of streams.¹⁴⁴
- Copper levels in 13.6 miles of the South Fork Koktuli River with direct effects, including death and stream avoidance, to more than 300,000 fish in the Pebble 2.0 scenario.¹⁴⁵

¹³⁹ *Id.* at 10.

¹⁴⁰ Though copper is responsible for most of the estimated toxicity, total metal toxicities, including impacts from aluminum, cadmium, cobalt, lead, manganese, selenium and zinc, are estimated to be significantly higher. EPA ASSESSMENT, *supra* note 3, at 8-32 to 8-34, 8-38.

¹⁴¹ The track record of U.S.-based porphyry copper mines also reveals an industry in which unplanned contaminant release is commonplace. A review of the 14 porphyry copper mines that have operated for at least 5 years in the United States found that all but one had experienced “reportable aqueous releases,” with such events ranging from three to 54. Releases of mine water have ranged from chronic uncaptured leachate release to acute events resulting from equipment malfunctions, heavy rains, or power failures. The record of analogous mines therefore indicates that “releases of water contaminated beyond permit limits would be likely over the life of any mine at the Pebble deposit.” *Id.* at 8-22.

¹⁴² *Id.* at 8-56. Invertebrates are a food source to immature salmon and all post-larval life stages of resident rainbow trout and Dolly Varden. Effects on invertebrates are therefore “highly relevant” to protecting salmon and other valued fish, and “protection of fish requires protection of sensitive invertebrates.” *Id.* at 8-55.

¹⁴³ *Id.* at 8-56.

¹⁴⁴ *Id.*

¹⁴⁵ *Id.* at 8-55.

- 100-fold copper exceedances in the Pebble 6.5 scenario, sufficient to directly affect more than a half million fish through aversion, sensory inhibition, inhibited development, or death in 26 to 31 miles of stream.¹⁴⁶ Under this scenario, copper is estimated to exceed chronic water quality criteria at all stations on the South Fork Koktuli River, two of six stations on the North Fork Koktuli River, and three of seven stations on Upper Talarik Creek.¹⁴⁷

The sources of water discharge under routine operations include effluents discharged from the treatment plant, uncollected leachates from the tailings storage facilities, and waste rock piles.¹⁴⁸ The hydraulic conductivity of the substrate material located near possible dam sites varies greatly, with “localized discontinuities” in the rate of groundwater conveyance resulting from fractured bedrock. This means that even a small number of flowpaths with hydraulic conductivity that is higher than expected could significantly increase the direction and quantity – and therefore the potential adverse effects – of leachate flow.¹⁴⁹

Even absent failure, these effects clearly meet the threshold for 404(c) action. When we add the risk of a Wastewater Treatment Plant (“WWTP”) failure, the effects to Bristol Bay are magnified significantly. The number of fish experiencing death or an equally detrimental effect such as loss of habitat from a WWTP failure would range from 10,000 to one million across scenarios. Stream lengths of 30, 62, and 62 miles would have copper concentrations sufficient to directly affect fish in the Pebble 0.25, 2.0, and 6.5 scenarios, respectively. And sensory inhibition or aversion would affect 600,000 to 1.4 million focal fish species.¹⁵⁰ Treatment plant failure in the Pebble 2.0 and Pebble 6.5 scenarios would cause copper levels directly affecting more than a half million of the focal fish, including 25 to 31 miles of “acute lethality to all life stages in most of the reaches.”¹⁵¹ The effects of a plant failure could be most devastating depending on its timing and duration, with the most severe adverse effects if it occurred during the period of salmon return.¹⁵²

The waste rock piles in EPA’s mine scenarios – based on those described in the Wardrop Report – do not include liners. Given the geological complexity and permeability of surficial layers, in the Pebble 2.0 mine, for example, only 84% of potentially acid-generating leachate and 82% of total waste rock leachate would be captured.¹⁵³ The remaining leachate, which would enter in Upper Talarik Creek, would be more than six times the acute lethal concentration for trout in the Pebble 2.0 scenario, and would require dilution by more than a factor of 10 to avoid acute lethality of trout in Pebble 6.5. Some invertebrates would only avoid chronic toxicity with dilution by a

¹⁴⁶ EPA ASSESSMENT, *supra* note 3, at 8-55.

¹⁴⁷ *Id.* at 8-38. Cadmium and zinc also exceed chronic criteria, but at fewer stations and by much smaller magnitudes. *Id.*

¹⁴⁸ *Id.* at 8-1.

¹⁴⁹ *Id.* at 8-11.

¹⁵⁰ *Id.* at 8-56.

¹⁵¹ *Id.*

¹⁵² EPA ASSESSMENT, *supra* note 3, at 8-55.

¹⁵³ *Id.* at 8-12.

factor of 490.¹⁵⁴ As discussed in Section III.B.2.b, using a liner as a “best practice” mitigation measure would be economically infeasible and insufficiently effective to prevent the harm.

Post-closure risks are also dramatic. After closure under the Pebble 0.25, 2.0, and 6.5 scenarios, the mine pit would fill with water for approximately 20, 80, and 300 years, respectively. Eventually, without collection and treatment, the pit water would be a source of leached minerals to streams. “Pit water composition cannot be predicted with any confidence, but some degree of leaching is *inevitable*.”¹⁵⁵ Post-closure water treatment failures are a challenge because they tend not to be promptly detected and corrected. In addition, because site hydrology and chemistry would change over time, “treatment requirements would change and the responses might be slow.”¹⁵⁶ To avoid exceeding the copper criteria, a leachate barrier or collection system for the Pebble 6.5 scenario would require *more than 99% effectiveness*, and predicting pit water quality has a high degree of uncertainty.¹⁵⁷ Seepage and leachate monitoring and collection systems, as well as the WWTP, might therefore need to be maintained for hundreds to thousands of years. It is “impossible” to evaluate the success of such long-term collection and treatment systems for mines because “no examples exist.” Such long timeframes “exceed both existing systems and most human institutions,”¹⁵⁸ and abandonment of the site would leave untreated leachate to flow to the streams draining the site, reaping havoc on the watershed ecosystems.

b) *Additional “Day-to-Day” Adverse Effects will Result from Temperature Modifications and Operation of the Transportation Corridor*

EPA describes several additional “day-to-day” routine and failure-driven adverse effects that would be expected from mining in Bristol Bay. First, interception of groundwater for mining purposes and release through a WWTP would cause “serious” population impacts by altering the complex ways in which groundwater feeds stream channels and impacting thermal heterogeneity.¹⁵⁹ Alteration of surface-water and groundwater flows from mine development and operation would impact water temperatures. Groundwater-surface water interaction supports thermal heterogeneity, which is closely linked to salmon migration, spawning and incubation. Treated water returning to streams would be expected to have different thermal characteristics than

¹⁵⁴ *Id.* at 8-50. EPA used the mean leachate concentration and assumed complete separation of NAG and PAG rock. If instead 5% of material in the NAG rock pile is PAG rock, as assumed in the Wardrop Report, leachate copper concentration estimates could be too low by factors of 2.8. *Id.* at 8-60.

¹⁵⁵ *Id.* at 8-22 (emphasis added).

¹⁵⁶ *Id.* at 8-21.

¹⁵⁷ *Id.* at 8-56, 6-33. As described in Section VI.B.2 of our last submission, copper standards and criteria are based on conventional test endpoints of survival, growth, and reproduction. However, as EPA notes, “research has shown that the olfactory sensitivity of salmon is diminished at copper concentrations lower than those that reduce conventional endpoints in salmon.” *Id.* at 8-28. These laboratory-based criteria are therefore not fully protective of the aquatic ecosystems, as field studies of streams contaminated by copper and other metals have shown. *Id.* at 8-35.

¹⁵⁸ EPA ASSESSMENT, *supra* note 3, at 6-32.

¹⁵⁹ *Id.* at 8-64.

water derived from groundwater sources.¹⁶⁰ Particularly troublesome is that despite these facts, the plan for a Pebble mine outlined in the Wardrop Report included a temperature control feature that meets only state standards – but which did not even attempt to match natural water temperature regimes.¹⁶¹

Next, EPA explicitly recognizes, as requested by the peer review panel, “that the transportation corridor and all associated ancillary development, including future resource developments made possible by the initial mining project, will necessarily and inevitably have impacts.”¹⁶² Potential risks to fish habitats and populations resulting from construction and operation of the transportation corridor – including filling and alteration of wetlands, stream crossings, fine sediments, dust deposition, runoff contaminants, and invasive species – are unacceptable by 404(c) standards. “Only rarely has it been possible to build roads that have no negative effects on streams.”¹⁶³ In Bristol Bay, risks to fish from construction and operation of the transportation corridor are particularly significant because of the hydrological complexity of the region. The construction and operation of the transportation corridor could “fundamentally alter” this balance, causing unacceptable adverse effects.¹⁶⁴

Specifically, the transportation corridor would cross 53 streams “known or likely to support” salmonids.¹⁶⁵ Culverts, which can cause severe interference with fish movement, would be constructed on 35 presumed salmonid streams.¹⁶⁶ Culvert failures would be common, particularly post-closure, and would block fish passage and degrade downstream habitat.¹⁶⁷ Approximately 11% of the transportation corridor would also intersect mapped wetlands: an additional 24% would be located within 100 m of wetlands, and another 16% would be located within 100 to 200 m of wetlands. Wetlands provide important salmonid resting, spawning, and rearing habitat, and support food abundance and diversity.¹⁶⁸ Product concentrate and diesel pipeline failures near streams would also be expected to occur during the life of a mine: “Both would cause acute lethal effects on invertebrates and fish, and the concentrate could create highly toxic sediment.”¹⁶⁹

The range of adverse effects of “day-to-day” operations and failures is wide, and the impacts are profound. Action to protect Bristol Bay is warranted—and essential.

¹⁶⁸ *Id.* at 10-19.

¹⁶⁹ *Id.* at 14-17.

6. Unacceptable Cumulative and Induced Impacts are Reasonably Foreseeable

EPA “[e]xplicitly recognize[d],” as requested by the peer review panel, “that the transportation corridor and all associated ancillary development – including future resource developments made possible by the initial mining project – will necessarily and inevitably have impacts” which will “expand geographically through time with further ‘development.’”¹⁷⁰ Defined as cumulative and induced effects, EPA carefully details the expansive impacts foreseeably associated with the development of an initial mine, providing a chilling image of a mine-bearing Bristol Bay watershed—an industrial dystopia that 404(c) was enacted to prevent.

The threshold for consideration of cumulative and induced impacts is “reasonable foreseeability.” Cumulative impacts are defined as “the impact on the environment [that] results from the incremental impact of the action when added to other past, present, and *reasonably foreseeable* future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions.”¹⁷¹ Induced effects contribute to the cumulative effects of an action, and are those “caused by the action and are later in time or farther removed in distance, but are still *reasonably foreseeable*.”¹⁷²

Cumulative and induced impacts are acute in the mining industry, and this is especially so in areas that are, like the Bristol Bay watershed, previously undeveloped and difficult to access. Once “the infrastructure for one mine is built, it [is] likely to facilitate the development of additional mines.”¹⁷³ Currently, the mineralized areas of Bristol Bay lack infrastructure, such as roads, utilities, and airports. This economic barrier to access and development would diminish upon construction of a first mine, making it reasonably foreseeable, if not inevitable, that the development of one will lead to the development of others.¹⁷⁴ Anadromous fish are particularly susceptible to regional-scale effects, because they migrate among freshwater habitats seasonally or between life stages. Suitable habitat in spawning areas, rearing areas, and along migration corridors is required for population stability. Loss or degradation of habitat in one location can therefore diminish the ability of other locations to support these species,¹⁷⁵ and adverse impacts can accrue even when fish are absent from a particular area.¹⁷⁶ Large-scale, human-caused modification of the landscape has contributed to the extinction risk for many native salmon populations in the Pacific Northwest.¹⁷⁷ It must not be permitted to do so in Bristol Bay.

¹⁷⁶ *Id.* at 13-6.

¹⁷⁷ *Id.*

a) *Cumulative Effects of Additional Mine Development Call for 404(c) Action*

EPA provides a rigorous analysis of the effects of additional mine development at several sites in the Nushagak River watershed, including the Pebble South/PEB, Big Chunk South, Big Chunk North, Groundhog, AUDN/Iliamna, and Humble claims. These were adeptly chosen as reasonably foreseeable mine sites, because they each contain copper deposits and have already generated exploratory interest.¹⁷⁸ If the six mine sites were developed, the cumulative area covered by their footprints could be 8,600 to 13,000 acres. Stream habitats lost to eliminated or blocked streams could extend 25 to 40 miles, and cumulative wetland losses could make up 1,800 to 6,100 acres. These are conservative estimates that do not include the hydrologic drawdown zones around each mine pit as was done for the Pebble scenarios. As a comparison, inclusion of the drawdown area in even the smallest Pebble 0.25 scenario increased the area of stream and wetlands losses by 84%.¹⁷⁹

Additional mines would also impact the region's wildlife, and its Alaska Native communities. Thirteen of the fourteen villages located in the watersheds would experience some impact on traditional subsistence use areas. More broadly, mine development would have cultural impacts on these communities, which until now have relied on fish and wildlife for subsistence.¹⁸⁰

Furthermore, not only are impacts from the day-to-day operations of multiple mines cumulative, but also the cumulative probability of failures – now and in the future – increases as the number of facilities increases. For example, “historical data suggest a *100% cumulative probability* of failure in one of the four pipelines over the life of the Pebble 2.0 scenario.”¹⁸¹ The existence of multiple mines also increases the chance that a single severe event could result in “common mode failures” (multiple failures with a common cause), such as earthquakes.¹⁸² The passage of time further enhances cumulative impacts, as post-closure site management considerations apply to each additional mine – each with its own ownership structure. Mines exist in perpetuity; human institutions do not:

Closure at each mine would typically require hundreds to thousands of years of monitoring, maintenance, and treatment of any water flowing off site. Given the magnitude of these timeframes, we would expect multiple and more frequent system failures in future years. In light of the relatively ephemeral nature of human institutions over these timeframes, *we would expect that monitoring, maintenance, and*

¹⁸¹ *Id.* at 13-30 (emphasis added).

¹⁸² *Id.* at 13-31.

*treatment would eventually cease, leading to increased release of contaminated waters downstream.*¹⁸³

b) Additional Development Induced by Mining Would Further Magnify the Adverse Effects on Bristol Bay

Presumably without intending to draw attention to the considerable additional non-mining impacts that a first mine would make possible, PLP called on EPA to focus less “narrowly on the Pebble deposit and future mining operations,” because doing so “ignores other stressors, impacts, and activities of concern” and fails EPA’s “commitment to addressing water quality problems in a comprehensive, holistic fashion.”¹⁸⁴ The agency delivered.

Cumulative impacts from induced development, or development resulting from the introduction of industry, roads, and infrastructure associated with mining, is a significant risk to Bristol Bay because it is “an iterative phenomenon.”¹⁸⁵ Each impact of development is itself an additional stressor. For example, increased employment opportunities lead to nearby community growth, which boosts housing demand, community infrastructure, and amenities. Enhanced accessibility from road and port construction reduces the cost of shipping fuel and freight to nearby areas; reduced shipping costs, in turn, make construction, business operation, recreation, tourism, and cost of living more affordable, again facilitating increased growth.¹⁸⁶

Each of the effects described in this section are reasonably foreseeable, would compound the impacts of mining well beyond their individual direct effect, and cumulatively are “unacceptable” under Section 404(c) of the Clean Water Act.

IV. THE BRISTOL BAY ECOSYSTEMS SHOULD NOT BE LEFT IN THE HANDS OF MINING COMPANIES THAT HAVE MISLED THE PUBLIC, THEIR INVESTORS, AND EPA

NDM and PLP seek to deflect attention from their financially-driven Pebble Mine interests by hurling repeated insults at EPA, implicitly (and explicitly) accusing it of improper motivation for studying the environmental impacts that will result from large-scale mining in the Bristol Bay watershed.¹⁸⁷ In reality, the agency’s Assessment is the direct result of repeated requests from federally-recognized tribes in the region, the

¹⁸³ *Id.* (emphasis added).

¹⁹³ Letter from Senator Maria Cantwell, to Elisse B. Walter, Chairman, U.S. Securities & Exchange Comm'n (Mar. 18, 2013), available at http://www.cantwell.senate.gov/public/_cache/files/169563c5-e840-4021-911d-74f63d55e13f/SEC%20pebble%20final%2003182013.pdf [hereinafter, "Senator Cantwell Letter"].

watershed, as they “reflect projects based on extensive exploration, assessment, and preliminary engineering, which are described in [the Wardrop Report] as ‘economically viable, technically feasible and permissible’.”¹⁹⁴

Yet, in order to block EPA’s efforts, PLP referred to the “very same Wardrop Report” as a “fantasy proposal” when it delivered formal testimony to the EPA in August of 2012,¹⁹⁵ and, in its submission to EPA regarding the first draft Assessment, as a “generic mine development scenario” that “today could not be legally built.”¹⁹⁶ These conflicting formal statements to two different federal agencies – statements that cannot both be true – leave the public, corporate investors, and two United States regulatory bodies to wonder if NDM is misleading its investors and the Securities and Exchange Commission, or intentionally providing contradictory testimony to EPA. Such blatant manipulation of critical facts renders EPA’s words of caution particularly salient:

The promises of today’s mine developers may not be carried through by future generations of operators whose sole obligation is to the shareholders of their time.¹⁹⁷

Furthermore, the dismal operational track record of Anglo American (“Anglo”) (50% PLP owner) belies Pebble’s claim that it “has always incorporated the *best* design and operational standards for physical project elements.”¹⁹⁸ Anglo has a track record of environmental pollution and damage to the health of local communities. For example, Anglo’s Iron Duke mine in Zimbabwe made part of a nearby river virtually fishless and was the likely cause of a “fish kill” resulting from mine effluent.¹⁹⁹ In a town near Anglo’s Black Mountain Mine in South Africa, children were found to have high blood lead levels that impaired their performance in school.²⁰⁰ Anglo’s mine in Ireland polluted sediment in nearby rivers, causing the Irish EPA to advise against fishing or allowing animals to drink from the rivers temporarily.²⁰¹ This warning came *after* Anglo worked to overcome local concerns about the environmental impacts of mining. In addition, a 2001 study of 34 mines around the world found that Anglo-owned mines had the highest

concentration of arsenic in their surface water.²⁰² The company's history abroad belies the company's promise to "co-exist" successfully²⁰³ with the salmon in Bristol Bay.

In fact, the regulatory mechanisms developed to protect against corporate irresponsibility cannot realistically be expected to hold these mining companies to their environmental obligations over the long term. Though operators of hardrock mining facilities in Alaska are required to demonstrate financial assurance for reclamation, waste management, and dam safety costs as a way of anticipating future need for remediation, the requirement cannot promise to guard against the risks associated with mine existence in perpetuity. First, the mine developer is required only to demonstrate financial assurance.²⁰⁴ When the human institution responsible for developing the mine is no longer in existence – a reasonable probability over the thousands of years that the mine will persist – such assurances mean little. Indeed, of the 10 operating, proposed, or closed Alaskan mines today, one has already gone into bankruptcy without adequate bonding to cover mine closure (Illinois Creek).²⁰⁵ Furthermore, even assuming long-term corporate management, financial assurance does not require coverage for chemical or tailings spills.²⁰⁶ Inevitably, where financial assurance is inadequate, it is the taxpayers who are left holding the proverbial bag for significant clean-up costs, unpaid by the mining companies whose assurances, however enthusiastically given, were never realized. And it is the local residents who must live with the environmental consequences.²⁰⁷

V. CONCLUSION

EPA's revised Watershed Assessment thoroughly documents that large-scale mining in Bristol Bay would irrevocably devastate one of the most highly-functioning and productive salmon ecosystems remaining anywhere in the world, as well as the sustainable communities, wildlife, and local economy that it supports. EPA's authority is clear: it may prevent dredge and fill projects "whenever" failure to do so would be

²⁰⁴ EPA ASSESSMENT, *supra* note 3, at 6-36.

²⁰⁵ As EPA notes:

Environmental impacts associated with premature closure may be more significant than impacts associated with planned closure, as mine facilities may not be at the end condition anticipated in the closure plan and there may be uncertainty about future re-opening of the mine. For example, PAG waste rock in our mine scenarios would likely still be on the surface in the event of a premature closure. If the mine closed because of a drop in commodity price, there would be little incentive to incur the cost of moving or processing millions of metric tons of PAG waste rock. Because premature closure is an unanticipated event, water treatment systems might be insufficient to treat the excessive and persistent volume of low pH water containing high metal concentrations.

²⁰⁶ *Id.* at 4-10.

²⁰⁷ *Id.*

reasonably likely to have an “unacceptable adverse effect” on fisheries and wildlife. These legal thresholds have been met –and surpassed – here.

Failure to stop the Pebble Mine and other large-scale mines would risk in Bristol Bay the fate of the Pacific Northwest, where development has led to the “near complete loss of wild salmon” and dependence on hatcheries – themselves a potential cause of further ecosystem degradation²⁰⁸ – to supplement salmon runs.²⁰⁹ The long-term nature of any mining project, the improbability that mining institutions would live up to their monitoring commitment (or even survive) for the *centuries* the mine would remain in existence, and the inevitable harm that large-scale mining would inflict on the region and its sensitive resources all contribute to a conclusion of unacceptable adverse effect on the future of Bristol Bay. As one peer reviewer noted, “[t]he risks seem, if anything, understated.”²¹⁰

EPA has clear legal authority and a solid factual basis to invoke Section 404(c) of the Clean Water Act to protect Bristol Bay. As EPA itself concluded, Bristol Bay is a “significant resource of global conservation value.”²¹¹ For all these reasons, we ask EPA to finalize the Watershed Assessment in 2013 and then act immediately to protect Bristol Bay under Section 404(c) of the Clean Water Act.

D. EPA May Not Engage in Cost-Benefit Analysis to Reach a Decision Under Section 404(c)	63
E. EPA May Invoke its 404(c) Authority Proactively to Prevent Large-Scale Mining in the Nushagak and Kvichak Drainages	65
IX. CONCLUSION.....	69

I. INTRODUCTION

On behalf of its 1.3 million members and activists, the Natural Resources Defense Council (“NRDC”) submits these comments to the U.S. Environmental Protection Agency (“EPA”) with respect to the agency’s May 18, 2012 draft Bristol Bay Watershed Assessment (“Watershed Assessment” or “Assessment”). The Assessment was prepared pursuant to EPA’s authority under section 104 of the Federal Clean Water Act (“FWPCA” or “Clean Water Act”) and specifically in response to petitions submitted under section 404(c) of the Act for EPA action to prohibit, deny, or restrict the specification of the proposed Pebble Mine site in Bristol Bay, Alaska as a disposal area for the discharge of dredged or fill material.

For the reasons discussed in detail below, NRDC believes that the Assessment is scientifically sound, analytically rigorous, and thoroughly documented, and that, together with the record on which it is based, it compellingly supports a determination that large-scale mining of the Pebble deposit is irreconcilable with the health and integrity of the fishery, drinking water, wildlife, and recreational resources of the Bristol Bay watershed. The watershed feeds one of the world’s most productive wild salmon fisheries, which supports indigenous people and their communities, a diverse array of wildlife, and a wide range of irreplaceable fishery and tourism-related economic and subsistence activities. Recognizing the unique importance of the area, offshore oil and gas exploration in Bristol Bay was banned in 2010, premised on the conclusion of federal regulators, as expressed at that time by U.S. Department of the Interior Secretary Ken Salazar, that Bristol Bay is “a national treasure that we must protect” and a resource “too special” to drill.¹

As EPA’s draft Watershed Assessment comprehensively documents, large-scale mining like the proposed Pebble Mine and its associated infrastructure and facilities would unavoidably threaten this “national treasure.” Given its sensitive and pristine location, the low-grade quality of the ore, the particular characteristics of the ore body, the complex and near-surface hydrology of the area, the exceptional fishery resources in the region, and the absence of supporting infrastructure, large-scale mining like that proposed at the Pebble Mine would inevitably result in “unacceptable adverse effects” to these critical natural and recreational resources, which is the regulatory threshold for initiating action under section 404(c).

More specifically, based on a rigorous scientific review and carefully considered analysis that consistently understates environmental risk, EPA makes a number of significant factual findings that are antithetical to any proposal for large-scale mining in the region, including development of the Pebble Mine. Those findings include:

- Inevitable and unavoidable harm to Bristol Bay salmon populations and fisheries due to habitat loss and degradation, downstream water flow reduction, population fragmentation, and reduced biodiversity;

¹ Press Release, U.S. Department of the Interior, Secretary Salazar Announces Comprehensive Strategy for Offshore Oil and Gas Development and Exploration (Mar. 31, 2010) [available at http://www.doi.gov/news/pressreleases/2010_03_31_release.cfm](http://www.doi.gov/news/pressreleases/2010_03_31_release.cfm) (hereinafter “U.S. Department of the Interior, Comprehensive Strategy”).

- Likely reduction in anadromous and resident salmon production due to road-derived sediments from a new 86-mile access road;
- Inhibition of salmon movement from culvert stream crossings, and a culvert blockage rate of 50% once the mine ceases operations;
- Diminished groundwater to surface water connectivity;
- 98% probability of a pipeline spill with potential contaminant release into streams and wetlands;
- Inevitable reductions to salmon-dependent wildlife;
- Serious threats to Alaska Native health, society, and culture;
- Risk of metal leaching and acid rock drainage, particularly after mine operations have ceased; and
- Catastrophic environmental impacts in the event of a tailings dam failure.

What is more, as is discussed in Sections VI.D and VI.E *infra*, EPA’s Assessment, if anything, actually underestimates potential risks due to its explicit exclusion of important risk factors. If included, those risk factors would unquestionably increase the intensity and duration of significant harm to the region and its resources, including most notably the Bristol Bay wild salmon fisheries. For example, EPA’s maximum mine scenario only estimates 6.5 billion tons of waste when, if fully developed, the waste at Pebble Mine would exceed 10 billion tons. In addition, EPA’s baseline analysis assumes no accidents, failures, or other releases of mining products or wastes, with reliable collection of all water from the site and effective treatment of effluents. This is deliberately and unrealistically conservative given that, in EPA’s words, “accidents and failures *always happen* in complex and long-lasting operations.”² Equally important, the Watershed Assessment does not consider the impacts that would result from the development and operation of a deep-water port in Cook Inlet, secondary development, and increased evapotranspiration, precipitation, and other likely consequences associated with climate change. It also severely underestimates the amount of tailings likely to be released during failure and the distance these tailings would travel. Taken together, these additional foreseeable risk factors unquestionably support a conclusion that EPA’s assessment of risk underestimates the actual harm attendant to large-scale mining in the Bristol Bay watershed.

Despite this underestimation of harm, the Watershed Assessment still concludes that large-scale mining in the Bristol Bay watershed would have enormous adverse environmental impacts. Under the circumstances, there is no question that EPA has both the authority and ability to prevent the predicted harm. Section 404(c) authorizes the agency to prohibit, deny, or restrict the use of an area as a disposal site for dredged or fill material when the discharge will have an “unacceptable adverse effect on municipal water supplies, shellfish beds and fishery

² U.S. EPA, An Assessment of Potential Mining Impacts on Salmon Ecosystems of Bristol Bay, Alaska (May 18, 2012) (hereinafter “EPA Assessment”), Vol. 1, 5-1 (emphasis added).

areas (including spawning and breeding areas), wildlife, or recreational areas.”³ Federally-recognized tribes in the region have requested that EPA use this authority to protect Bristol Bay from large-scale sulfide mining like the Pebble Mine,⁴ and their request has been followed by similar requests, including from the Bristol Bay Native Corporation (the largest development corporation and private land-owner in the Bristol Bay region, representing approximately 9,000 shareholders), commercial fishing interests represented by the Alaska Independent Fishermen’s Marketing Association and the Bristol Bay Regional Seafood Development Association, the National Council of Churches, sportsmen’s groups, chefs and restaurant owners, and conservation organizations. In addition, the Bristol Bay Native Association (a non-profit corporation and tribal consortium representing the 31 federally-recognized tribes in the Bristol Bay region) approved resolutions requesting EPA to use its authority under section 404(c) to protect Bristol Bay.⁵

The Watershed Assessment documents not just the basis for but the necessity of EPA action to protect the water and recreational resources of the Bristol Bay watershed from certain devastation. As described more fully below, therefore, we urge EPA to finalize its Watershed Assessment and move forward expeditiously to prohibit large-scale mining in the region, including the Pebble Mine.

II. OVERVIEW OF THE BRISTOL BAY REGION

The Bristol Bay watershed is characterized by short, warm summers and long, cold winters, with annual average temperatures hovering around freezing.⁶ Rain is moderate, and ranges from 460-810 mm annually.⁷ The landscape has been shaped by past glaciations and the dominant eco-region type is tundra.⁸ About 7,600 people live in the region, in communities ranging in size and character from small rural villages to the region’s largest city, Dillingham.⁹ Approximately 70% of Bristol Bay residents are Alaska Natives (compared to 14.8%

³ 33 U.S.C. § 1344(c) (2006).

⁴ Six federally-recognized tribes originally petitioned EPA. Those six petitioner tribes are Nondalton Tribal Council, Koliganik Village Council, New Stuyahok Traditional Council, Ekwok Village Council, Curyung Tribal Council and the Levelock Village Council. See A Joint Letter from Six Federally-Recognized Tribes in the Kvichak and Nushagak River Drainages of Southwest Alaska to Lisa P. Jackson, Administrator of the U.S. EPA (May 2, 2010) (hereinafter “Letter from Six Federally-Recognized Tribes”). EPA later received additional requests from Ekuik Village Council, Clarks Point Tribal Council, and Twin Hills Village Council (collectively “Tribes”).

⁵ Bristol Bay Native Association, A Resolution Requesting the EPA to Invoke Section 404(c) of the Clean Water Act as Appropriate in the Kvichak and Nushagak Drainages of the Bristol Bay Watershed to Protect Habitat and Existing Uses, Res. 2010-32 (Sept. 17, 2010) (on file with author) (hereinafter “Bristol Bay Native Association, Res. 2010-32”); Bristol Bay Native Association, A Resolution in Support of BBNC’s Recommendations for Proactive EPA Action to Protect the Waters and Salmon of Bristol Bay, Res. 2012-04 (Mar. 23, 2012) (on file with author) (hereinafter “Bristol Bay Native Association, Res. 2012-04”).

statewide),¹⁰ and the principal economic activities in the region are related to commercial, recreational, and subsistence fisheries.¹¹ The Bristol Bay region is home to thirty-one federally-recognized tribes.¹²

Alaska Natives in Bristol Bay still overwhelmingly utilize and rely on subsistence hunting and fishing, collecting an estimated 2.1 million pounds of usable subsistence harvest per year.¹³ The dollar value on this harvest is difficult to estimate, but has been placed at between \$68 and \$194 million.¹⁴ Salmon accounts for over one-half of all subsistence harvest by Bristol Bay residents.¹⁵ Many residents mix cash and subsistence livelihoods, and commercial salmon fishing – the preferred commercial occupation – is the primary source of cash income for Bristol Bay residents.¹⁶

The Bristol Bay region lies near the “Ring of Fire”¹⁷ and is known for significant volcanic and tectonic activity. Regular earthquakes also occur in the region, and in 1964 the region experienced the largest earthquake ever recorded in North America.¹⁸ The Shumagin seismic gap, located along the Alaska Peninsula, is believed to have a very high probability of a major earthquake within the next few decades.¹⁹

The 40,000 square mile Bristol Bay watershed is considered an intact eco-region and has been formally recognized for the special quality of its natural resources by the creation of two national parks – Lake Clark National Park and Katmai National Park and Preserve – and the largest state park in the country, Wood Tikchik State Park. The largest fresh water body in Alaska – Lake Iliamna – is found just 25 miles to the southeast of the proposed Pebble Mine site.²⁰ The watershed is home to 35 types of fish, more than 190 birds, and more than 40 terrestrial animals.²¹

Bristol Bay – and the streams and rivers that feed it – is world renowned for the productivity and diversity of its salmon fisheries. It supports globally important commercial fisheries, and provides habitat for shorebirds, waterfowl, marine mammals,²² and five species of

²² The Nature Conservancy in Alaska, Ecoregional Assessment, *supra* note 6, at 9.

Pacific Salmon²³ — including the largest sockeye salmon fishery in the world,²⁴ and the third largest King salmon run.²⁵ The Nushagak River and Kvichak River watersheds yield approximately half of the Bristol Bay sockeye salmon production.²⁶ These fish are anadromous; they hatch and rear in freshwater systems, migrate to the sea to grow to adult size, and return to freshwater systems to spawn and die.²⁷ The watershed provides habitat to several other anadromous species, including steelhead, rainbow smelt, and dolly varden.²⁸ Resident fish also include Arctic Grayling, Northern pike, multiple species of trout, Arctic Char, and whitefish.²⁹

The exceptional quality of the Bristol Bay watershed fish populations is largely a result of its high-quality, diverse aquatic habitats, the hydrologic and biochemical connectivity between surface and subsurface waters, and the relatively little human development.³⁰ However, the region is not immune to outside ecological pressures; in the past 25 years, for example, some anadromous fish populations have declined, and marine productivity has decreased in the region, possibly due to rising temperatures.³¹

In addition to the fisheries, the region is known for its healthy populations of top-level predator species³² and its high biological productivity, in part due to the exchange of nutrients between the Bering Sea and freshwater and terrestrial habitats in Bristol Bay.³³ Numerous mammals thrive in the Bristol Bay watershed, including brown and black bears, wolves, wolverines, and lynxes.³⁴ The lowlands of Bristol Bay provide important habitat for many other species of mammals, including foxes, martens, beavers, and moose.³⁵ A study of Lake Clark National Park, located just northeast of Lake Iliamna, estimated that between 35 and 40 species of mammals could be found in the park.³⁶ The study focused on small mammals³⁷ and noted that some of the species found in the area included bats, several species of shrews, pikas and hares, and at least nine species of rodents.³⁸

²³ Id.; EPA Assessment, Vol. 1, ES-5. The watershed supports production of all five species of Pacific salmon found in North America: sockeye (*Oncorhynchus nerka*), coho (*O. kisutch*), Chinook or king (*O. tshawytscha*), chum (*O. keta*), and pink (*O. gorbuscha*).

²⁴ The Nature Conservancy in Alaska, Ecoregional Assessment, supra note 6, at 9; EPA Assessment, Vol. 1, ES-5. The fishery represents approximately 46% of the average global abundance of wild sockeye salmon.

The Bristol Bay watershed is a particularly important region for caribou. The Mulchatna Caribou herd – the third largest in Alaska – ranges throughout the Bristol Bay region. Its numbers have fluctuated greatly: in 1997 the herd was estimated to contain 200,000 caribou³⁹ – over one-fifth of the state’s estimated 900,000 wild caribou⁴⁰ – but had decreased to roughly 30,000 caribou by 2008.⁴¹ Several other herds make use of the region, including the Kilbuck, Nushagak, and North Alaska Peninsula herds.⁴²

The region is also an important area for birds, including bald eagles. Its coastal wetlands, lagoons, and bays provide staging areas for large seasonal aggregations of waterfowl and shorebirds, such as the Beringian marbled godwit, Aleutian tern, and red-faced cormorant.⁴³ A number of bays within Bristol Bay have seasonal concentrations of over 100,000 birds, and three lagoons host concentrations of over 500,000 birds annually.⁴⁴ Furthermore, the Bristol Bay region provides wintering habitat for several other important bird species, including the Emperor goose, King eider, Steller’s eider, and McKay’s bunting.⁴⁵

The Bay itself also supports diverse populations of marine species. More than 30 species of groundfish and shellfish depend on the bay,⁴⁶ including scallops, crab, and shrimp.⁴⁷ Pacific herring and pacific halibut are found in the region,⁴⁸ and the bay is also home to many marine mammals, including the Bristol Bay population of beluga whales, killer whales, gray whales, the endangered Steller’s sea lion, Pacific walruses, two species of seals, and sea otters.⁴⁹ Lake Iliamna is home to freshwater harbor seals – one of very few seal populations worldwide to establish a permanent year-round presence in a freshwater environment.⁵⁰

Considered together, these resources comprise a highly functioning, healthy, diverse, and naturally and economically sustainable ecosystem that, without exaggeration, can be characterized as unsurpassed anywhere in the world. It is truly, in the words of Interior Secretary Salazar, “a national treasure” that deserves and requires our protection.⁵¹

III. HISTORY OF THE PEBBLE MINE PROJECT

In July 2006, Northern Dynasty Minerals (“NDM”) first applied for water rights permits in preparation for site exploration and construction of the Pebble Mine.⁵² In September 2006, NDM submitted corrections to its surface water applications which were requested by the Alaska Department of Natural Resources (DNR).⁵³ Then, on September 5, 2006, NDM submitted its “Initial Application Package for Constructing a Dam,” that, under state law, initiates the application process for a certificate of approval for new dam construction in Alaska.⁵⁴ NDM requested permission to build two tailings⁵⁵ impoundments, A and G, which would contain the billions of tons of tailings to be generated by the project. Next, NDM submitted a separate application for ground water rights for the same area covered by the surface water applications.⁵⁶ In October 2006, DNR sent a letter to NDM announcing that its consistency review packet was complete and that the consistency review would begin the following day.⁵⁷

On the same day, NDM responded to DNR by first acknowledging the notification that its consistency review package was complete, but nevertheless requesting that DNR suspend the consistency review until further notice. NDM’s stated reason for seeking a hiatus in the application process was the need to gather more environmental data.⁵⁸

⁵² On July 7, 2006, Northern Dynasty filed Application for Water Right: South Fork Koktuli River (LAS 25874), Application for Water Right: North Fork Koktuli River (LAS 25871), and Application for Water Right: Upper Talarik Creek (LAS 25876).⁵² Alaska Department of Natural Resources, Division of Mining Land and Water, Pebble Project – Water Right Applications, accessed at <http://dnr.alaska.gov/mlw/mining/largemine/pebble/water-right-apps/index.cfm>. The State of Alaska’s Department of Natural Resources (DNR) responded to Northern Dynasty’s submission by stating that the submission was incomplete. The Alaska DNR requested, among other things, that Northern Dynasty submit more information for their proposals to use ground water, submit separate proposals for the use of surface water, and correct the name of the second proposal from North Fork Koktuli River to Unnamed Tributary of the North Fork Koktuli River. On July 26, 2006, the Alaska DNR issued three documents in response to Northern Dynasty’s three submitted documents: ADNR Analysis of Application Completeness of July 7, 2006 Application for Surface Water Right: South Fork Koktuli River, ADNR Analysis of Application Completeness of July 7, 2006 Application for Surface Water Right: North Fork Koktuli River and ADNR Analysis of Application Completeness of July 7, 2006 Application for Surface Water Right. *Id.*

⁵³ NDM submitted Response to July 26, 2006 ADNR Analysis of Application Completeness of July 7, 2006 Application for Surface Water Right: Unnamed Tributary (NK1.190) North Fork Koktuli River (Sept. 21, 2006), Response to July 26, 2006 ADNR Analysis of Application Completeness of July 7, 2006 Application for Surface Water Right: South Fork Koktuli River (Sept. 21, 2006) and Response to July 26, 2006 ADNR Analysis of Application Completeness of July 7, 2006 Application for Surface Water Right: Upper Talarik Creek (Sept. 21, 2006). Alaska Department of Natural Resources, *supra* note 52.

⁵⁸ *Id.*

In August 2007, a wholly-owned subsidiary of Anglo-American PLC, a United Kingdom-based mining company, entered into a 50% partnership with a wholly-owned subsidiary of NDM to form the Pebble Limited Partnership (“PLP”).⁵⁹ In order to retain its 50% interest in the PLP, Anglo-American is required to continue its staged investment of \$1.425 billion to advance Pebble Mine toward permitting and operations. Both NDM and Anglo-American have equal rights of management, operatorship, and control in the PLP.⁶⁰

In February 2011, NDM released a “Preliminary Assessment of the Pebble Project, Southwest Alaska” (“Wardrop report”) that updated and substantially revised the project’s economic analysis and environmental footprint.⁶¹ The Wardrop report described a “large industrial facility” – an open pit mine, underground mining, tailings facilities, and associated infrastructure – located “within a vast region of Alaska notable for its undeveloped wilderness, isolated and sparsely populated communities, Alaska Native culture and traditional ways of life, significant salmon fisheries, and other fish and wildlife populations.”⁶² It contemplated three development cases – 25, 45 and 78-year plans – and selected the 45-year case as the “base case” for the Preliminary Assessment. Notably, although the Wardrop report only described development scenarios for the first 25 years,⁶³ it simultaneously concluded that “even the 78-year Resource Case would exploit only 55% of the total resource.”⁶⁴

In February 2012, PLP released an “Environmental Baseline Document” (“EBD”) intended to characterize the environmental studies conducted by PLP or its predecessors at Pebble from 2004 to 2008.⁶⁵ Fully financed by PLP, the EBD purports to describe the existing physical and chemical (climate, water quality, trace elements), biological (wetlands, fish and aquatic invertebrates, wildlife, habitat), and social environments (land and water use, socio-economics, subsistence) within the Bristol Bay and Cook Inlet regions where development of the Pebble Mine is proposed. The EBD has not been subject to independent peer review.

IV. DESCRIPTION OF THE PROPOSED PEBBLE MINE

PLP plans to build an enormous gold, copper, and molybdenum mine at the headwaters of Bristol Bay. Located between Katmai National Park to the south and Lake Clark National Park to the north,⁶⁶ the proposed Pebble Mine would be sited 25 miles north of Lake Iliamna –

⁵⁹ Press Release, Anglo American PLC, Anglo American Has Become a 50% Partner with the northern Dynasty Partnership in the Pebble-Copper-Colg-Molybdenum Project in Southwestern Alaska, By Making a Staged Cash Investment of US\$1.425 Billion (Aug. 1, 2007), [available at http://www.angloamerican.com/media/releases/2007pr/2007-08-01](http://www.angloamerican.com/media/releases/2007pr/2007-08-01).

the largest freshwater lake in Alaska, a crucial incubator of Bristol Bay's wild salmon fishery, and a haven for a rare colony of freshwater seals as well as numerous other species.⁶⁷ The proposed Pebble Mine would be located in the Nushagak and Kvichak river drainages, a rich salmon spawning ground.⁶⁸ The mine footprint would cover at least 54 square miles (on 90 square miles of state land) and would include both an underground block caving mine at the Pebble East Deposit and an above-ground open pit mine at the Pebble West Deposit.⁶⁹ The total size of the mine has yet to be publicly disclosed and exploration is still ongoing,⁷⁰ with more of the potential mine deposit still being explored.⁷¹ PLP has submitted no permit applications since NDM's 2006 water rights application. Although a final mine plan has not been released, EPA can nonetheless reasonably ascertain the scope and impacts of any large-scale mining operation in the Bristol Bay watershed given the nature of the mineral deposits, the requirements for successful mining development, and publicly available information about potential mining activity.⁷²

A. The Underground and Open Pit Mines

An underground mine 5,000 feet deep is proposed at the Pebble East Deposit, to be accessed by block caving – a method that poses severe environmental risks to the surrounding landscape, water quality, and wildlife. With this approach, a main haulage shaft is dug beneath the deposit, the ore body above the haulage shaft is weakened with explosives, and then gravity forces the rubble into the haulage shaft from which it is removed.⁷³ This process can cause large amounts of subsidence, with a range of associated environmental impacts, including, for example, collapse of surface materials, degraded water quality, lowered water table, and chronically unstable ground.⁷⁴

An open pit mine is proposed to access the ore lying closer to the surface at the Pebble West Deposit.⁷⁵ As described in 2006, the open pit would be at least 2 miles wide and 1,700 feet deep.⁷⁶ More recently, the 2011 Wardrop report described a 25-year mine plan that included an open pit over two miles wide and 2,500 feet deep⁷⁷ – which, if constructed, would make it one of the largest mines in the world and the largest open pit mine in North America.⁷⁸ EPA estimated that an open pit would encompass a surface area between 5.5 and 17.8 km² at a depth of between 2,625 and 3,937 feet.⁷⁹ The open pit mine is expected to generate significant amounts of dust from its operations due to the blasting, hauling and drilling, and material handling,⁸⁰ as well as unspecified quantities of acid mine drainage from billions of tons of waste rock.⁸¹

B. The Tailings and the Tailings Dams

The proposed Pebble Mine is projected to generate at least 10 billion tons of waste rock that will be stored at the mine site.⁸² In its Assessment, however, EPA severely underestimates this amount, characterizing the maximum mine scenario at only 6.5 billion tons.⁸³ This waste rock, or tailings, will contain sulfides, including pyrite,⁸⁴ which will comprise 3% of the total tailings.⁸⁵ Overall, sulfides will constitute 5% to 10% of the mine’s tailings.⁸⁶ When sulfuric minerals are exposed to air and water, they oxidize and create acid mine drainage, which can, as discussed below, significantly decrease the pH levels of the watershed and make the affected streams uninhabitable for salmon and other aquatic organisms.⁸⁷

To hold the waste, NDM proposed in 2006 to construct two tailings storage facilities located on an unnamed tributary of the North Fork Kaktuli River and the upper reaches of the

Questa mine, “[b]y 2002, the maximum depth of surface subsidence in Goat Hill Gulch was ~200 feet.” *Id.* at 2. He also discussed massive surface subsidence in Blodgett & Kuipers, Underground Hard-Rock Mining, *supra* note 73, at 5, and reported that at the Inspiration Copper Mine, “the subsidence had lowered the ground surface from 50-300 feet[.]” *Id.* at 12. For an example of a rubble-ized subsidence, see Blodgett, Subsidence Impacts, *supra*, at 4.

South Fork Kaktuli basin. The dam on the South Fork of the Kaktuli River – denominated tailings impoundment A – would hold roughly 2 billion tons of tailings solids.⁸⁸ Three embankments – raised in stages to their maximum height as the mining progresses – would ultimately reach heights of 700, 710, and 740 feet. Tailings impoundment G, on an unnamed tributary of the North Fork of the Kaktuli River, would include two dams, at 450 and 175 feet high, and hold approximately 500 million tons of tailings solids.⁸⁹ The total lengths of these dams as projected in 2006 would be 9 miles, and the tailings compounds would cover 7,600 acres, or 12 square miles.⁹⁰ The largest of the embankments for tailings impoundment A – at 740 feet high and 4.3 miles long – would possibly be the largest dam in the world.⁹¹ The dams would be built in stages. After a dam is filled at each stage, the height would be raised to the next level.⁹² With capacity to hold only 2 billion (of the projected 10 billion) tons of mine waste, the tailings storage facilities would nevertheless completely submerge Frying Pan Lake. NDM has conceded that additional tailings sites and dams would be needed as the size of the deposit expands.⁹³

In 2011, NDM disclosed a new design for the tailings facilities.⁹⁴ Based on a 25-year mine plan, the Wardrop report described an enlarged tailings storage facility at Site G (“TSF G”). Created by three embankments – at 685, 400 and 100 feet – TSF G would hold approximately 2 billion tons of tailings.⁹⁵ As noted above, this would not supply enough tailings storage for either the 45-year “base case” upon which NDM based its financial analysis or the total anticipated waste in excess of 10 billion tons.

V. HISTORY OF THE EPA BRISTOL BAY WATERSHED ASSESSMENT

A. The Native Tribes’ Petition

In May 2010, six federally-recognized tribes from the Bristol Bay region – including the Nondalton Tribal Council, Koliganik Tribal Council, New Stuyahok Traditional Council, Ekwok Village Council, Curyung (Dillingham) Tribal Council and the Levelock Village Council – sent a letter to EPA requesting that it proactively initiate a section 404(c) action to protect the Bristol Bay watershed before PLP could develop further plans for the Pebble Mine.⁹⁶ The need for the

⁹⁴ Wardrop, Preliminary Assessment, *supra* note 61, at 49-52.

⁹⁵ Id. at 49-50.

⁹⁶ Letter from Six Federally-Recognized Tribes, *supra* note 4. Ultimately, EPA received petitions from nine federally recognized tribes, BBNC, commercial fishermen, sportsmen, conservationists, and others to initiate action under section 404(c).

petitions arose out of the adoption in 2005 by the Alaska DNR of a land use plan for the Bristol Bay area. Although that plan was ostensibly intended to make the state permit review process more efficient,⁹⁷ DNR's process for developing the land use plan – and the resulting land use plan itself – were deeply flawed, including, among other things, its designation of the Pebble Mine site as land best suited for mineral development.⁹⁸

The process laid out sixteen possible categories for land use in the Bristol Bay region. Although one of the major uses of land for Bristol Bay residents is supporting their subsistence lifestyle (an average of 80% of protein consumed by residents comes from fish and wildlife subsistence sources⁹⁹), subsistence use was not included as a category.¹⁰⁰ Furthermore, the category for Fish and Wildlife Habitat and Harvest Areas focused largely on marine resources and did not include moose or caribou among the species that could be considered for the designation, despite the fact that both species are harvested by both native and non-native hunters and are a part of subsistence use.¹⁰¹ Finally, while DNR did include a category for recreational use, it excluded hunting and fishing from its definition of recreation.¹⁰²

Most directly relevant here is the fact that, although the land on which the Pebble Mine would be located is used predominantly by local residents to support a subsistence lifestyle and by others for recreation based around fishing and hunting, DNR's land use plan ignored those current uses and elected instead to prioritize mineral extraction. In addition, the land use plan flies in the face of the 45-year history of state and federal efforts to conserve the Kvichak and Nushagak river drainages.¹⁰³ Because the Army Corps will consider and likely rely on this fundamentally flawed land use plan in its decision whether to grant a permit for the Pebble Mine, petitioner Tribes determined that EPA's intervention under section 404(c) is essential.¹⁰⁴

In August 2010, the Bristol Bay Native Corporation sent a letter requesting that EPA protect Bristol Bay under section 404(c).¹⁰⁵ EPA received additional requests from Ekuk Village Council, Clarks Point Tribal Council, and Twin Hills Village Council, and received letters

¹⁰⁴ The Native Tribes' letter laid out various reasons why proactive action by EPA is necessary, including (1) the health of the Kvichak and Nushagak River drainages is essential to the wellbeing of the salmon on which Alaska Natives subsist and would be put at risk by permitting the Pebble Mine; (2) the PLP has terminated its Technical Working Group, used to consult with federal and state officials about the environmental impact of the mine, and that the termination (and lack of cooperation that it reflects) will create an unacceptable information deficit for state and federal officials as the project review proceeds; and (3) the land's flawed classification of the site as mineral land – despite major subsistence and recreation uses – may result in the Army Corps issuing a permit for the Pebble Mine based on a fundamentally erroneous premise. Letter from Six Federally-Recognized Tribes, supra note 4.

supporting the initiation of a 404(c) action from the Alaska Independent Fishermen’s Marketing Association, the Bristol Bay Regional Seafood Development Association, the National Council of Churches, and numerous other sportsmen and conservation groups.¹⁰⁶ The Bristol Bay Native Association also approved resolutions requesting EPA to use its authority under section 404(c) to protect Bristol Bay.¹⁰⁷

B. Procedural Background of the EPA Watershed Assessment

In response to the concerns raised by Native Tribes and others, EPA announced on February 7, 2011 that it would conduct “a scientific assessment of the Bristol Bay watershed to better understand how future large-scale development projects may affect water quality and Bristol Bay’s salmon fishery[.]”¹⁰⁸ EPA’s regional administrator explained that the Bristol Bay watershed “is essential to the health, environment and economy of Alaska,” and that “[g]athering data and getting public input now, before development occurs” would assure that future decisions by the agency “are grounded in the best science and information and in touch with the needs of these communities.”¹⁰⁹

On May 18, 2012, after fifteen months of scientific review and analysis, EPA released for public comment a “draft scientific study of the Bristol Bay watershed and its natural resources.”¹¹⁰ The Assessment was conducted and released in response to “growing interest in large-scale mining in the watershed from a number of stakeholders and local communities with a range of views[.]”¹¹¹ EPA’s stated goals for undertaking the Watershed Assessment are to attain a better understanding of potential environmental impacts of mining activities on the watershed,¹¹² and to provide a “sound scientific and technical foundation for future decision making.”¹¹³

Upon release of its Assessment, EPA announced that the draft would be subject to a 66-day public comment period, eight public hearings,¹¹⁴ and independent scientific peer review. An

¹¹³ Notice of the Peer Review Meeting for EPA’s Draft Report Entitled an Assessment of Potential Mining Impacts on Salmon Ecosystems of Bristol Bay, AK, 77 Fed. Reg. 40,037-01 (July 6, 2012).

¹¹⁴ Public hearings were held from May 31, 2012 to June 7, 2012 in Seattle, Anchorage, Dillingham, Naknek, Levelock, Igiugig, Nondalton, and New Stuyahok. United States Department of Environmental Protection, Bristol Bay webpage, accessed at <http://yosemite.epa.gov/R10/ECOCOMM.NSF/bristol+bay/bristolbay>.

independent contractor assembled the peer review panel, whose names were announced on June 5, 2012. The panel's draft charge questions were simultaneously released for a three-week public comment period.¹¹⁵ Peer review of the Watershed Assessment will take place from August 7 to August 9, 2012. Members of the public may observe the first two days of the proceedings and provide oral testimony on August 7.¹¹⁶

C. Scope and Findings of the EPA Watershed Assessment

EPA has explained that its Assessment “does not provide an in-depth assessment of a specific mining project,” but rather reviews the environmental impacts that could result from mining activities “at a scale and with the characteristics that are realistically anticipated, given the nature of mineral deposits in the watershed, the requirements for successful mining development, and publicly available information about potential mining activity.”¹¹⁷ In other words, the environmental impacts identified in the Assessment would result from *any* economically viable mine in the area. And though not an analysis of the Pebble Mine specifically, this “publicly available information” about “potential mining activity” to which EPA refers is the baseline data and plans developed by PLP.¹¹⁸

EPA analyzed two mine scenarios – a “minimum” and “maximum” mine size – based on the amount of ore processed (2 billion vs. 6.5 billion metric tons) and mine life spans (25 to 78 years). The minimum mine would include a 1,358 acre mine pit to hold 2 billion tons of tailings; a 3,686-acre tailings impoundment behind a 685-foot-high earthen dam; a 3,286-acre waste rock pile; and an 86-mile road, with four pipelines running product concentrate, return water, diesel, and natural gas.¹¹⁹ The maximum size mine – the “most likely” mine to be developed – is based on the Wardrop report.¹²⁰ It would include a pit and waste rock pile of a combined 9,486 acre area, potentially an underground mine, and three tailings impoundments, with a combined area of 10,807 acres.¹²¹

EPA's analysis first considers “routine operation,” which assumes no engineering failures during operation or in the centuries after operation — an assumption that EPA cautions is unrealistic because accidents and failures of some kind are a certainty in mining.¹²² Yet even assuming flawless planning, engineering, operation, and maintenance, EPA's Watershed Assessment anticipates severe impacts to the Bristol Bay environment. Loss of headwater stream and wetland areas in the mine footprint will destroy critical salmon habitat and spawning and rearing areas. Downstream water flow reduction will irreparably degrade salmon populations and

¹¹⁵ An Assessment of Potential Mining Impacts on Salmon Ecosystems of Bristol Bay, Alaska—Peer Review Panel Members and Charge Questions, 77 Fed. Reg. 33,213-02 (June 5, 2012).

¹¹⁶ Notice of the Peer Review Meeting for EPA's Draft Report Entitled an Assessment of Potential Mining Impacts on Salmon Ecosystems of Bristol Bay, AK, 77 Fed. Reg. 40,037-01 (July 6, 2012).

¹¹⁷ Press Release, EPA Region 10, [EPA Releases for Public Comment Draft Scientific Study of Bristol Bay Watershed](http://yosemite.epa.gov/opa/admpress.nsf/d96f984dfb3ff7718525735900400c29/6979fe30fc6583f385257a020061b472!OpenDocument) (May 18, 2012), available at <http://yosemite.epa.gov/opa/admpress.nsf/d96f984dfb3ff7718525735900400c29/6979fe30fc6583f385257a020061b472!OpenDocument>.

fisheries and damage one of the very keys to salmon health and volume in this area — their biodiversity. Operation of a mine would also require the construction of an access road, causing detrimental impacts to salmon through population fragmentation, exposure to sediment, and decreased groundwater-surface water connectivity. Furthermore, salmon prevalence supports ecosystem strength as a whole, and degraded salmon populations would impair the region’s wildlife. Alaska Natives would also suffer health and cultural harm from mining, as their way of life has for centuries depended on salmon for subsistence, as well as for cultural, social, and spiritual identity.

EPA next moves from the inevitable impacts of “routine” mining to describing the environmental impacts of failures that have occurred in other mines and have the potential to occur here. Again, the Assessment identifies significant adverse impacts. Culvert failure has a 50% probability, and pipeline spills of chemicals have a 98% probability. The long-term effectiveness of tailings dams is unproven, and due to the “ephemeral” nature of human institutions over time, EPA expects maintenance and treatment of the mine site to eventually terminate.¹²³ This could have detrimental and indefinite consequences on the surrounding environment due to acid mine drainage and metal leaching. And if a tailings dam failure were to occur, catastrophic damage extending hundreds of miles – and hundreds of years – can be expected.

The Watershed Assessment is also notable for what it omits. EPA elected to exclude consideration of certain significant mining-related environmental stressors from which additional and likely *greater* impacts will result. Indeed, undervaluations of potential harm pervade the report. For instance, the Watershed Assessment estimates the maximum mine scenario at 6.5 billion tons, which is significantly smaller than the over 10 billion ton resource estimate in the Wardrop report. In addition, the development and operation of a deep-water port in Cook Inlet, secondary development, and increased evapotranspiration, precipitation, and likely other consequences of climate change are all absent from the analysis. This intentionally conservative approach only serves to bolster the Assessment’s significance as a directive for proactive EPA action in Bristol Bay because, despite its conservatism, the report identifies substantial impacts of mining that will cause unacceptable adverse effects on the Bristol Bay environment.

VI. THE WATERSHED ASSESSMENT AND RECORD ON WHICH IT IS BASED ESTABLISH THAT MINING WOULD HAVE UNACCEPTABLE ADVERSE IMPACTS ON THE BRISTOL BAY ENVIRONMENT

If the Pebble Mine or other large-scale mining development is permitted in Bristol Bay, there is a high likelihood of unacceptable adverse effects to local fisheries, wildlife, and municipal waters, three of the central resources that section 404(c) is designed to protect.¹²⁴ EPA’s Watershed Assessment in fact reveals that the unacceptable environmental damage

¹²³ *Id.* at Vol. 1, 7-14.

¹²⁴ Our focus on these factors is not meant to suggest that the effects of the mine with respect to other 404(c) factors – such as shellfish beds and recreation – are irrelevant, but only to emphasize that the impacts to local fisheries, wildlife, and water will be particularly severe. Furthermore, the available research particularly stresses the impacts to fisheries, wildlife, and water, many of which also adversely affect recreation. While it is known that shellfish are abundant in the area, and common sense would indicate that decrease in water quality will impact these shellfish, data on these impacts are less well developed.

resulting from “routine” mining operations is not just likely – it is “inevitable and foreseeable.”¹²⁵ EPA defines “routine” as a best case scenario of no accidents, failures, or other releases of mining products or wastes, with “reliable collection” of all water from the site, and “effective treatment” of effluents.¹²⁶ The agency properly highlights, however, that this is *not realistic* “because accidents and failures *always happen* in complex and long-lasting operations.”¹²⁷ When just a few of the possible “accidents and failures [] likely to occur over the decades that a mine is in operation, and over the centuries that a [tailings storage facility] remains in the post-closure period”¹²⁸ are incorporated into the analysis, the results are catastrophic.

A mine and its associated transportation corridor would inevitably carve out huge swaths of land from the region, eliminate and modify salmonid habitat, and alter the water flow in the area, causing serious reductions in the region’s salmon population. Declining salmon populations would be detrimental to the productive Bristol Bay sockeye salmon fishery and would negatively impact the aquatic and terrestrial ecosystems of the region, which depend on salmon for nutrients. Severe downstream pollution of the watershed is also highly likely.

The inevitable and the likely adverse effects identified in the Watershed Assessment, while each individually significant and adverse, do not reflect the full extent of probable harm. EPA’s judicious Assessment is by design a conservative underestimation of projected environmental damage that would result from mining in Bristol Bay. These undervaluations range from data considerations such as maximum mine scenario,¹²⁹ stream length of anadromous fish habitat,¹³⁰ spawning salmon abundance,¹³¹ and salmon olfactory sensibility,¹³² to the blanket exclusion from analysis of the significant infrastructure that would be associated with mine development. Though power generation and transmission, secondary development, and – critically – construction and operation of a deepwater port at Cook Inlet “could have significant repercussions for the Bristol Bay ecosystem[,]” they were not considered.¹³³ The port alone would threaten a highly endangered, genetically distinct, and geographically isolated species of beluga whales. The mine and new road would also increase traffic to the region and undoubtedly spur industrialization and development as major infrastructure is introduced. This would enable not only the Pebble Mine but other large-scale mining in the region, as well as secondary development – *the most significant* of impacts for Bristol Bay¹³⁴ – to further compound the impacts to fragile fish and wildlife populations.

¹²⁵ EPA Assessment, Vol. 1, ES-14.

¹²⁶ *Id.* at Vol. 1, 8-1.

¹²⁷ *Id.* at Vol. 1, 5-1 (emphasis added).

¹²⁸ *Id.* at Vol. 1, 4-37.

¹³⁰ *Id.* at Vol. 1, 2-20.

¹³¹ *Id.* at Vol. 1, 5-10.

¹³² *Id.* at Vol. 1, 5-56.

¹³³ *Id.* at Vol. 1, 3-2. Other possible accidents excluded from consideration were spills of process chemicals on site or during transportation, failure of a tailings slurry pipeline, diesel fuel spills, waste rock slides or erosion, fires, and explosions. *Id.* at 6-1.

¹³⁴ *Id.* at Vol. 3, App. G at 9.

Furthermore, no matter how the mine is built and operated, the post-closure results are likely catastrophic. There are simply *no examples* of successful long-term treatment systems for inactive mines.¹³⁵ A review of recent pipeline spills in North America found that neither existing technology nor contemporary practice assure against catastrophic spills.¹³⁶ Today Bristol Bay is a watershed of superb quality, diverse aquatic habitats, high surface and subsurface water connectivity, and diverse and stable fish habitats, “untouched by human-engineered structures and flow management controls.”¹³⁷ Our urgent concern is for the Bristol Bay of tomorrow should the region be opened to large-scale mining development.

Our comments follow EPA’s tiered structure, analyzing first the inevitable and then the likely consequences of mining the Pebble deposit, followed by a discussion of possible catastrophic failure. Our subsequent sections describe the additional – and often *more* significant adverse impacts – of mining associated infrastructure and activities that EPA elected to omit from its analysis.

A. Adverse Impacts of Mining in Bristol Bay are Inevitable

1. Loss of Headwater Stream and Wetland Areas in the Mine Footprint Will Eliminate and Modify Critical Salmonid Habitat

If a mining project such as the Pebble Mine is permitted in Bristol Bay, even idealized failure-free operations would inevitably cause severe impacts on salmon habitat. The mine would eliminate headwater streams within and upstream of the mine footprint¹³⁸ and degrade downstream habitat through loss of headwater streams and wetlands.¹³⁹ Under the EPA minimum mine size scenario, 87.5 km of first- through third- order streams and 10.2 km² of wetland habitat would be eliminated or blocked. At maximum size, the mine would eliminate 141.4 stream kilometers and 17.3 km² of wetlands.¹⁴⁰ These numbers reflect uncertainty only to the extent that they may undervalue stream length and wetland area affected.¹⁴¹ Degradation at this level would eliminate or block 7% (minimum mine scenario) to 10% (maximum mine scenario) of the watershed’s total anadromous stream kilometers, home to coho salmon, sockeye salmon, Chinook salmon, and Dolly Varden spawning and rearing habitats.¹⁴²

¹³⁵ *Id.* at Vol. 1, 4-31, 5-45.

¹³⁶ *Id.* at Vol. 3, App. G at 14.

¹³⁷ *Id.* at Vol. 1, ES-8.

¹³⁸ The mine footprint consists of the area devoted to mining, including the mine pit, waste rock piles, TSFs, ore processing facilities, and other mine-related constructs. *Id.* at Vol. 1, 5-12.

¹³⁹ A wetland is classified as eliminated if it falls within the boundaries of the mine pit, waste rock pile, or tailings storage facility. *Id.* at Vol. 1, 5-14.

¹⁴⁰ *Id.* at Vol. 1, 5-14.

¹⁴¹ *Id.* at Vol. 1, 5-14, Box 5-1. The Assessment underestimates the amount of habitat that would be lost to mining. It excludes certain areas from the mine footprint, bases its estimate of stream losses on a dataset that underestimates the reach and extent of streams in the vicinity, and bases its estimate of wetland losses on maps that underrepresent the amount of wetland and aquatic areas within PLP’s mine mapping area. Comments of Thomas Yocom, Comments of Bristol Bay Native Corporation on the U.S. Environmental Protection Agency Draft Bristol Bay Watershed Assessment, Appendix A (Jul. 23, 2012).

¹⁴² *Id.* at Vol. 1, 5-16, 8-1.

While Northern Dynasty decries as “myth” the EPA determination that fishery damage could result from a “modern” mine “occupying less than one-twentieth of 1% of the land base,”¹⁴³ EPA has correctly emphasized that loss of relatively small portions of documented and anadromous headwater streams would have severe implications for fish well outside that geographical area.¹⁴⁴ The Alaska Bureau of Land Management recognized this fact as early as 1971, when it published findings that “seemingly ‘minor’ spawning areas may produce up to sixty percent or more of the total Kvichak run[.]”¹⁴⁵

The headwater streams at risk of elimination provide necessary fish spawning habitat to coho salmon in the North and South Fork Kookutli River watersheds, and to coho and sockeye salmon in the Upper Talarik Creek watershed.¹⁴⁶ They also offer essential rearing habitat to Chum salmon, sockeye salmon, Chinook salmon, coho salmon, rainbow trout and others, all known to rear within and upstream of the mine footprint.¹⁴⁷ In the most comprehensive published field inventory, one or more relevant fish species was detected in 96 percent of the 108 small waters sampled in the Nushagak and Kvichak River drainages in the Pebble vicinity.¹⁴⁸ Indeed, small headwater streams “collectively [] produce millions of salmon and determine water flow and chemistry of larger rivers.”¹⁴⁹

And these impacts are larger than at first glance. While the mine will outright eliminate some populations of salmon, many aspects of the mine – such as the mine site itself, the access road, and the pipelines – will also cause habitat fragmentation in salmon populations.¹⁵⁰ Smaller populations are more vulnerable to extirpation,¹⁵¹ causing greater impacts to local salmon populations. This elimination of many small populations of salmon would have crucial effects on the fishery. Bristol Bay’s salmon fishery is made up of many distinct, locally adapted populations,¹⁵² and the success and health of the Bristol Bay fishery depends on the fact that different populations do well in different years.¹⁵³ It is estimated that the Bristol Bay salmon return is over twice as stable due to this diversity than if it were made up of only one

population.¹⁵⁴ In fact, the Bristol Bay sockeye salmon population is in reality a combination of hundreds of genetically distinct populations, “each adapted to specific, localized environmental conditions.”¹⁵⁵ This diversity is “critical” to keeping the fishery stable and productive,¹⁵⁶ and without it, annual variability of sockeye salmon runs would more than double, causing more frequent fishery closures.¹⁵⁷ The proposed Pebble Mine has the potential to greatly reduce this diversity, just as other once-robust salmon fisheries have suffered biodiversity losses – and associated population declines – as a result of mining.¹⁵⁸

2. Salmon Populations and Municipal Groundwater Will be Severely Impacted by Streamflow Changes

Large scale flow reductions in the watershed would be part and parcel of any mining operation undertaken in Bristol Bay. With the documentation for its 2006 water permit applications, NDM requested the use of up to 35 billion gallons of water each year.¹⁵⁹ This would require that all surface and ground water within the area be redirected to mine use,¹⁶⁰ consistent with the EPA water capture scenario at start-up.¹⁶¹ During operation, EPA’s analysis of the downstream effects of mining found streamflow reductions of up to 32% (maximum mine scenario) and 63% (minimum mine scenario), even factoring in operational flow return to streams.¹⁶² Once the mine is closed, treated water from the pit would not be available for streamflow for at least 100-300 years.¹⁶³

Flow reduction is detrimental to salmon survival. At each stage of the EPA models, flow reductions would occur across Upper Talarik Creek and North and South Fork Koktuli watersheds of a magnitude significant enough to change ecosystem structures and functions.¹⁶⁴ Above the mine, fish stocks would be completely destroyed; downstream from the mine stream, flow reductions would diminish and degrade fish habitats.¹⁶⁵ Since the number of fish produced is determined by the quality and quantity of habitat available, this loss of flow is likely to cause reductions in resident and anadromous fish populations.¹⁶⁶ Sockeye, coho, and Chinook salmon spend at least a year rearing in freshwater before migrating to the ocean, and therefore depend on

the availability and quality of freshwater more than species that migrate shortly after hatching.¹⁶⁷ Low flow conditions are recognized as a potentially limiting factor in salmon populations and affect all life stages of fish.¹⁶⁸

The effects of low flow conditions are not limited to the risks they present to salmonid spawning and rearing habitat.¹⁶⁹ Loss of streamflow would also affect connectivity between the main channel and off-channel habitats, cause fish stranding or isolation if reductions exceed typical recession rates, reduce macroinvertebrate production, and increase fragmentation of stream habitats through increased frequency and duration of stream drying.¹⁷⁰ The elimination of streams caused by the mine and the corresponding decrease in flow volumes downstream would result in greater competition for resources — especially food and cover — among fish in the region.¹⁷¹ Loss of connectivity to wetlands, which contribute refugia and food supply, would further impact fish populations.¹⁷²

Reduction of the extensive connectivity that exists between groundwater and surface water in the Nushagak River and Kvichak River watersheds is also a great concern. Groundwater is a key water supplier to the upper sections of the streams in the region.¹⁷³ NDM's 2004 Environmental Studies and their 2006 water rights application show that groundwater from the mine area is an important contributor to stream flow.¹⁷⁴ Water temperature data collected by PLP and published in its EBD indicates that streams in the watershed are influenced by upstream lakes and groundwater contributions.¹⁷⁵ Groundwater-infused streamflow from headwater tributaries is critical to fish that remain in streams during the winter, as well as egg development and hatch and emergence timing, because it moderates mainstem temperature, reducing both winter freezing and summer heating.¹⁷⁶ Headwater streams and wetlands also contribute “disproportionately” to groundwater recharge by sending nutrients, water, organic material, and macroinvertebrates to higher order streams in the watershed, as well as invertebrate and detritus exportation downstream – an important energy subsidy for juvenile salmonids.¹⁷⁷

In light of this connectivity, PLP studies that identify numerous seeps in the streams draining the TSF 3, mine pit, and waste rock pile footprints offer disturbing evidence that the Pebble Mine would have direct impacts on groundwater sources¹⁷⁸ — and there is no easy engineering “fix.” The inherent complexity of the groundwater-surface water interactions would render uncertain any proposal to regulate or control these effects during large-scale development.¹⁷⁹

Changes in streamflow or streamflow sources can also lead to stream temperature changes – a particular threat to salmon. Temperature controls the metabolism and behavior of salmon, and fluctuations can produce vulnerability to disease, competition, predation, or death.¹⁸⁰ Migration, spawning, and incubation timing are closely tied to seasonal water temperatures. This contributes to the diversity of spawning migration in Bristol Bay, and, in turn, to the persistent nature of sockeye salmon populations and extended nutritional availability to wildlife.¹⁸¹ Temperature also influences the amount of dissolved oxygen in streams, with lower flow rates generally leading to less dissolved oxygen, which is a key limiting factor for fish survival.¹⁸²

Finally, low flow conditions will cause negative impacts to salmon from a general reduction in velocity¹⁸³ and reduced downstream water quality from sediment deposition.¹⁸⁴ Overall, it is likely that the mine’s water flow reductions would limit salmon growth and survival, leading to increased infection rates and crowding, and, in turn, to heightened competition and predation.¹⁸⁵

3. Operation of a Transportation Corridor Would Fragment and Diminish the Quality of Salmonid Habitat

The Bristol Bay watershed is located in “one of the last remaining virtually roadless regions in the United States,”¹⁸⁶ and development of a mine there would be impossible without dramatic transportation infrastructure expansion.¹⁸⁷ The 2011 Wardrop report discussed plans to construct an 86-mile access road connecting the mine to a proposed port at Iniskin Bay in Cook Inlet.¹⁸⁸ According to several studies, this road would cross at least 89 streams¹⁸⁹ and require up to 120 stream crossings.¹⁹⁰ Twenty-four of these streams are documented to provide 1,200 acres of spawning habitat for sockeyes and other salmonids.¹⁹¹ EPA’s mine scenario similarly provides for an 86-mile permanent access road connecting the mine site to a new port in Cook Inlet.¹⁹² This road is estimated to cross 34 streams and rivers that support salmonids within the Kvichak River watershed, including 17 streams designated as anadromous waters at the location of the crossing.¹⁹³

¹⁹³ *Id.* at Vol. 1, 5-60.

a. Siltation, Sedimentation, and Other Stream Modification Impacts are Likely to Disrupt Anadromous and Resident Salmon Production

Siltation, hydrologic modification, filling of wetlands, and road salts are “likely to diminish” anadromous and resident salmonid production in more than 30 streams.¹⁹⁴ The habitat potentially affected below the road crossings totals 270 km of stream, plus an additional 240 km upstream, if culverts impede fish movement.¹⁹⁵ It is “well-recognized” that management of roads in the type of terrain found in the Pebble prospect area can be “unpredictable and challenging,” due to difficulty anticipating the “extent and nature of disruption” to subsurface flow paths, and because “the effects of water table deformation can project hundreds of meters from the road itself.”¹⁹⁶ Roads can impact the connectivity between groundwater and surface water systems and, along with pipelines, fundamentally alter the “intricate connections between shallow aquifers and surface channels and ponds,” causing further impacts on surface water hydrology, water quality, and fish habitat.¹⁹⁷

Furthermore, the sediment contribution from roads frequently far surpasses that from all other land management activities combined. Road-derived fine sediments have been linked to decreased fry emergence, decreased juvenile densities, loss of winter carrying capacity, increased predation on fishes, and reduced benthic organism populations and algal production. It could render otherwise suitable spawning gravel useless, and impact the concentrated spawning sockeye salmon populations in the shallow waters of Lake Iliamna.¹⁹⁸ Salts and other materials used to treat roads can also wash off into streams, rivers, and wetlands, causing direct exposure to fish and their invertebrate prey.¹⁹⁹

b. Culverts Are Likely to Fragment Habitat and Impede Salmon Movement

Though listed as a “possible” failure by EPA, the Assessment’s projections reveal that culvert interference with fish movement is in fact a highly likely result of mining – projected by EPA to eventually impact 50% of culverts.²⁰⁰ Under any mine scenario, many stream crossings will likely be culverts instead of bridges; EPA anticipates fourteen.²⁰¹ Culverts can serve as a barrier to fish, restrict or eliminate fish movement to upstream habitat, and isolate or modify populations.²⁰² Such habitat fragmentation increases the chance that fish populations will be extirpated due to a lack of genetic diversity or chance events.²⁰³ Culvert interference with fish movement can occur in several ways. The crossings can create excessive water velocities and disorienting turbulence — or the water running through the culvert can be too shallow for fish to

²⁰³ Id.

traverse.²⁰⁴ Culverts can further block fish movement as a result of outfall barriers, channel scouring and erosion, lack of resting pools below culverts, or a combination of conditions.²⁰⁵

In a healthy watershed, salmon often move into seasonal floodplain wetlands and small valley floor tributaries to escape main-channel flood flow stresses. The existence of culverts reduces flow to these safe havens because flow is instead directed into the main channel.²⁰⁶ And even if fish can physically swim through a culvert, there may be “behavioral barriers” that prevent fish from attempting passage, as fish will often avoid long culverts, darkness, confined spaces, and shallow depths.²⁰⁷

Even assuming compliance with fish passage guidelines at installation, culverts will likely threaten salmon migration in the future.²⁰⁸ Blockages and erosional failure are common features of culverts, and without prompt repair can cause the loss of a year class if they occur during migrations.²⁰⁹ Road maintenance during mine operation should generally catch such failures in a timely manner, but without “continual and proper” maintenance, culverts fail and become barriers to fish passage.²¹⁰ Because “typical” road inspection and maintenance practice declines post-closure, the likelihood of partial or entire culvert blockage after mining ends jumps to a dramatic 50%.²¹¹ This means that seven of the fourteen potential salmonid-supporting streams with culverts in the risk area would experience post-closure blockage, resulting in the likely loss of the streams’ ability to support long-term populations and resident species such as rainbow trout or Dolly Varden.²¹²

4. If Salmon Fisheries Are Degraded, Degradation of the Entire Ecosystem and Adverse Effects to Wildlife Will Follow

Salmon are a resource base “that supports much of the coastal ecosystem.”²¹³ They have been called a “keystone”²¹⁴ and “cornerstone” species²¹⁵ due to their importance to the greater ecosystem. Because a wide number of animals feed on salmon²¹⁶ – and because salmon hugely

affect ecosystem productivity and regional biodiversity due to nutrient transportation²¹⁷ – what harms salmon harms the wildlife that depend on them. EPA has stressed that the inevitable reduction in salmon production caused by potential mining in Bristol Bay would also lead to roughly proportionate reductions in wildlife that feed on salmon, including brown bears, wolves, and bald eagles.²¹⁸ While this proportionate loss ratio alone would generate unacceptable effects on wildlife, the far-reaching impact of salmon throughout the local ecosystem suggests losses of a much greater magnitude.

Salmon are invaluable to the ecosystem as a food source. Numerous species consume salmon at all life stages, from salmon eggs to spawned-out carcasses.²¹⁹ Salmon provide food sources to all types of terrestrial mammals, including carnivores and “herbivores,”²²⁰ many types of birds,²²¹ and a wide variety of fish.²²² They are also an important food resource to several marine species, such as beluga whales and sea lions, which will follow salmon hundreds of kilometers upstream.²²³ Salmon are important to more than megafauna; algae, fungi, bacteria, and many populations of invertebrates feed on salmon carcasses and in turn affect the greater ecosystem.²²⁴ Scientists believe that the presence of salmon, and the seasonal nature of their availability, has shaped the evolution of aquatic and terrestrial consumers, including in many cases a co-evolution between predators and prey.²²⁵

Salmon are also crucial to the ecosystem because they transport nutrients into freshwater ecosystems. Salmon serve as a “conveyor belt,” carrying nutrients to these ecosystems.²²⁶ They accumulate over 95% of their biomass in the ocean,²²⁷ and, when they return to freshwater, a “large fraction” of their marine-derived nutrients (“MDN”) are incorporated into freshwater and terrestrial food webs.²²⁸ Because salmon can migrate over 1,000 kilometers inland, these nutrient gains benefit a wide geographic area.²²⁹

Any reduction in salmon populations might severely impact this conveyor belt, as it has been predicted that the presence of salmon creates a positive feedback loop. Nutrients brought by spawning salmon enhance juvenile salmon growth and survivorship because, in aquatic salmon ecosystems, primary production is often severely nutrient-limited.²³⁰ Declining numbers of spawning salmon can thus impede juvenile salmon survival, reducing yet further the nutrients in affected ecosystems.²³¹

Returning and spawning salmon are also important to wildlife because their MDN “fuel much of the productivity of the Bristol Bay watershed.”²³² Salmon predators such as bears deposit those MDN on the landscape, where they increase plant production that supports moose, caribou, song birds, and other terrestrial wildlife.²³³ Non-mammals such as birds and insects are also responsible for transporting salmon away from streams,²³⁴ and the transported carcass is consumed by a variety of scavengers in the terrestrial ecosystem.²³⁵ Nutrients leach into the soils by excretion and decomposition, and are taken up by the vegetation.²³⁶ It is thought that salmon play a significant role in the productivity of riparian ecosystems.²³⁷

Salmon’s contributions extend yet farther and deeper into the surrounding ecosystem. For example, since bear densities are correlated with salmon availability, and bears are important seed dispersers, the presence of salmon leads to better dispersal of seeds.²³⁸ As another example, salmon can cause higher densities of insectivorous birds, which eat insects that destroy vegetation. Increased salmon, then, often leads to increased vegetation.²³⁹

Finally, salmon act as ecosystems engineers. They are an important source of mechanical energy, and intensively and regularly disturb benthic communities. This alters the composition of sediments and changes the topography of the substrate, which has many effects on the ecosystem, including increasing the survival of salmon eggs.²⁴⁰ In this multitude of ways, salmon strengthen – and their decline would degrade – the surrounding wildlife.

5. Degradation of Salmon Habitat Would Have Significant Negative Impacts on Alaska Native Cultures

Alaska Natives and Bristol Bay residents in the watershed depend – and have for generations – on salmon for their subsistence. Reduced salmon stocks would seriously threaten

their health, way of life, and the survival of their communities. Subsistence-based living is vital to Alaska Native identity, and plays a central economic, social, and cultural role.²⁴¹ Two of the last intact, sustainable salmon-based cultures in the world, the Yup'ik and Dena'ina, live in the Kvichak and Nushagak River watersheds.²⁴²

In Bristol Bay, an average of 80% of protein consumed by residents comes from fish and wildlife subsistence sources, or over 300 pounds of subsistence meats per person per year.²⁴³ Salmon constitute over half of this total subsistence harvest.²⁴⁴ Nearly everyone in most rural Bristol Bay communities uses meat gathered through subsistence hunting; those who do not hunt receive the meat through communal resource distribution networks. For instance, 88% of the area's population reported consuming caribou meat, and 86% reported consuming moose.²⁴⁵ In addition to these meats and salmon, Bristol Bay residents also harvest small mammals, birds and their eggs, and plants.²⁴⁶ As explained above, *all* of these sources would suffer negative impacts from a reduction in salmon quantity and quality. "Any salmon-mediated effects on subsistence wildlife resources in the area would have corresponding impacts on subsistence users."²⁴⁷

Significant negative impacts on salmon or other subsistence resources would also negatively impact Alaska Native health and culture. Subsistence resources are deeply connected to mental and emotional health related to traditional culture, language and traditional expression of interpersonal and land relationships, and nutrition and physical health.²⁴⁸ The Alaska Native cultures living in the proposed mine area have significant ties to these specific land and water resources, which have evolved over *thousands* of years. It would simply "not [be] possible to replace elsewhere these subsistence use areas lost to mine operations."²⁴⁹ The importance of salmon to the region's indigenous cultures cannot be understated. "The people in this region not only rely on salmon for a large proportion of their highly nutritional food resources; salmon is also integral to the language, spirituality, and social relationships of the culture."²⁵⁰

²⁵⁰ Id. at Vol. 1, 6-46.

B. Adverse Impacts of Mining the Pebble Deposits are Likely

1. A Mine Would Cause Severe Downstream Pollution through Use and Transport of a Wide Range of Chemicals

Although EPA categorizes a pipeline spill as a “possible” failure, the Assessment itself reveals that a spill is more properly analyzed as a foreseeable cost of operation — because it is a near certainty. The probability of a spill from a pipeline transporting copper-gold slurry, diesel, and natural gas between the mine and port site is 98% in 25 years.²⁵¹ In only two minutes (a conservative premise that assumes successful automatic shutoff), the pipeline would be expected to release 366,000 L of leachate — a leachate that would exceed limits for six metals, including exceedance of the copper acute criterion by a factor of more than 700.²⁵² As discussed in more detail below, copper exposure renders salmon unresponsive to alarm cues, less aware of proximal danger, and therefore less prepared to avoid or evade attack, or once attack is initiated, to successfully evade the predator.²⁵³

A spill could occur at any point of the pipeline. There is a 16% probability that it would enter a stream within the Kvichak watershed, and a 23.4% probability of entering a wetland.²⁵⁴ If entering a stream, the concentrate would kill fish and invertebrates both immediately and in the long-term. Physical effects could include embeddedness in riffle and spawning areas and increased stream turbidities.²⁵⁵ A spill could also lead to long-term bio-uptake and transfer of metals within the food chain.²⁵⁶ Settled concentrate turned toxic sediment would spend years making its way through streams and finally to Iliamna Lake, where it could be toxic to the eggs and larvae of sockeye salmon.²⁵⁷ Though the precise composition of the product concentrate and its leachate is uncertain, it would certainly be high in copper and sulfur, making it “implausible” that it would be nontoxic to aquatic biota.²⁵⁸ “Depending on the size, time and location of a pipeline spill, a slurry pipeline break could impact thousands to hundreds of thousands of adult salmon and high-value resident fish – and hundreds of thousands to millions of juvenile fish.”²⁵⁹

Though not addressed in the Assessment, a mine in the Pebble area would utilize a wide variety of ecologically harmful substances, such as explosives, fuels and oils, antifreeze, water treatment chemicals, herbicides and pesticides, and road de-icing compounds, any of which may be released into surface and ground water.²⁶⁰ Spills of these chemicals could cause “critical” impacts if they occurred in spawning or rearing habitats,²⁶¹ or cause particular harm when occurring simultaneously with other mine impacts.

²⁶¹ The Nature Conservancy, Ecological Risk to Wild Salmon, *supra* note 18, at 65.

Furthermore, cyanide is often used during mining of copper, gold, and molybdenum.²⁶² Much of the information on cyanide indicates that it breaks down quickly and mostly harmlessly—but this is neither complete nor correct.²⁶³ Cyanide should be listed as a potential concern whenever it is used in mining,²⁶⁴ because it reacts readily with almost any other available chemical and can form hundreds of compounds, many of which can persist in the environment.²⁶⁵ These compounds can accumulate in plants and can be chronically toxic to fish. As a result, it is “likely that the negative impacts to aquatic organisms, especially sensitive fish populations, from releases of cyanide...is underestimated and undetected....”²⁶⁶

2. Salmon Will Be Severely Impacted by Metal Leaching and Acid Mine Drainage.

Metal leaching and acid rock drainage is “the most costly and potentially environmentally damaging issue facing the mining industry,” and, as the EPA Watershed Assessment and any number of studies show, the proposed Pebble Mine is no exception.²⁶⁷ The rock associated with most metal mines, including the Pebble deposits, contains iron and other metal sulfides, which generate sulfuric acid when exposed to air and water.²⁶⁸ Sulfuric acid causes acidification of nearby surface waters and dissolves metals in the surrounding rock, mobilizing them into solution. Some of these metals, such as arsenic, cadmium, copper, and lead, become available to the food chain and can threaten the surrounding ecosystems.²⁶⁹ As EPA explains, copper is the major resource metal in the Pebble deposits and is “particularly toxic to aquatic organisms.”²⁷⁰ Metal leaching and acid rock drainage can originate from various aspects of the mine, including mine waste rock, tailings, and mine structures such as open pits.²⁷¹

²⁶⁶ Id. For example, a tailings impoundment in Romania containing a slurry with high concentrations of cyanide and heavy metals experienced a 20- to 25-m breach, and released 100,000 m³ of contaminated water into two rivers as a result of heavy rains and a sudden thaw caused overtopping of the embankment. Contamination reached the Danube River and the Black Sea, destroying aquatic species in over 1,900 km of the river system. EPA Assessment, Vol. 1, 4-41.

²⁷¹ U.S. EPA, Acid Mine Drainage Prediction 2 1994, available at <http://water.epa.gov/polwaste/nps/upload/amd.pdf>; EPA Assessment, Vol. 3, App. H at 10.

EPA's analysis under routine operations presumes that all runoff water, leachate, and wastewater would be collected and properly treated according to state and federal criteria prior to release.²⁷² As explained above, these assumptions are intentionally conservative and unrealistically underestimate risk. The agency's concrete findings reveal instead that unacceptable releases are likely to occur both during operation and more severely after closure.

Acid mine or rock drainage has been a "common phenomenon at mines around the world."²⁷³ It results in the elimination of fish and invertebrates from streams and, even after dilution has taken place, reduced abundance, production, and diversity of stream and river ecosystems.²⁷⁴ In the case of the Pebble deposits, there is significant potential for acid mine drainage.²⁷⁵ The likelihood of such drainage is predicted by measuring the ratio of rocks with acid-forming minerals to rocks with neutralizing minerals.²⁷⁶ Over 95% of the 399 samples taken from the proposed Pebble Mine area have been found to be acid-generating.²⁷⁷ Furthermore, the Pebble deposits are located in an area with moderate precipitation, a high water table, countless small streams and tributaries, and geological formations that are susceptible to ground water movement, making acid drainage "highly likely."²⁷⁸

Experimental leachates from Pre-Tertiary waste rocks of the Pebble deposit are acidic and would require collection and treatment. The Tertiary waste rocks in the Pebble area tend to be neutral and would therefore be used for construction of the tailings dam, to line the edges of the TSF, and for other fill purposes²⁷⁹ – *despite the fact* that they exceed the acute and chronic national ambient water quality criteria for copper.²⁸⁰ In other words, not only might failure to collect Pre-Tertiary waste rock leachate cause acid rock drainage, but even leachate from mine structures would require treatment to avoid toxic effects of metal leaching.²⁸¹ Yet during operation and planned post-closure period, failure of the water collection and treatment system is expected to be a "relatively common occurrence of limited duration."²⁸²

²⁸² *Id.* at Vol. 1, 6-38.

Worse, after the mine has closed, it would no longer be dewatered and would fill, generating an enormous mixture of waste rock leachate and ambient water, until precipitation and groundwater flow equilibrated.²⁸³ Once full, the pit contents would flow to a stream, most likely the Upper Talarik Creek, becoming its stream source.²⁸⁴ In theory, collection and treatment should continue until the composition of the site is stable. In practice, mines commonly close or are abandoned prematurely, leaving acidic materials on the surface, and untreated leachate discharge.²⁸⁵ Under these circumstances, EPA deems “certain” the likelihood of water collection and treatment failures, finding that “[w]hen water is no longer managed, untreated leachates would flow into the streams.”²⁸⁶ And as EPA explains, “[w]eathering to the point where [] contaminants are present in only trace amounts (at levels approaching their pre-mining background concentrations) would likely take hundreds to thousands of years, resulting in a need for management of materials and leachate over that time.”²⁸⁷

When, for whatever reason, the costs or obligations of mitigation or remediation are passed from the mining companies to public agencies (e.g., several recent large-scale mines in the U.S. have declared bankruptcy),²⁸⁸ taxpayers necessarily must assume the responsibility of ongoing management, including ensuring that polluted water is treated and the integrity of the mine is maintained – forever.²⁸⁹ As EPA powerfully articulated:

Human institutions change... Priorities are likely to change in the face of financial crises, changing markets for metals, new information about the resource, political priorities, or any number of currently unforeseeable changes in circumstance. The promises of today’s mine developers may not be carried through by future generations of operators whose sole obligation is to the shareholders of their time.²⁹⁰

Impacts from acid rock drainage can be extremely long lasting and have continued to emanate from mines in Europe, for example, that were established over 1,500 years ago.²⁹¹ There are also many challenges associated with mitigation,²⁹² the successes of which are questionable.²⁹³ One 2006 study, which examined acid rock drainage in 25 hard rock mines in the United States, found that nearly all of the mines that subsequently developed acid drainage

²⁸⁹ Id.

²⁹⁰ EPA Assessment, Vol. 1, 8-13. As a corollary, EPA also adroitly points out that it is “too soon” to know whether mines that are permitted for perpetual water collection and treatment such as the Red Dog Mine in Alaska can successfully do so in perpetuity. Id. at Vol. 1, 6-41.

²⁹¹ Jennings, *supra* note 276, at 4.

²⁹² Among other factors, mitigation requires large amounts of data collection and must continue forever. This means mine structures are subject to extreme design, monitoring, maintenance, and repair requirements. See William A. Price, The Mitigation of Acid Rock Drainage: Four Case Studies from British Columbia 1, available at <http://www.techtransfer.osmre.gov/nttmainsite/Library/proceed/sudbury2003/sudbury03/125.pdf>.

²⁹³ James R. Kuipers and Ann S. Maest, Comparison of Predicted and Actual Water Quality at Hardrock Mines: The reliability of predictions in Environmental Impact Statements, *supra* note 264, at ES-15.

underestimated or ignored the potential for acid drainage.²⁹⁴ In addition, when the mine was near surface or ground water and there was a high potential for acid drainage – both true for the Pebble deposits – the surrounding water had an overwhelming likelihood of contamination.²⁹⁵ The risk at the proposed Pebble Mine is additionally acute; as described in the Wardrop report, one of the proposed tailings storage areas is highly permeable and saturated. This means that the seepage cutoff walls and seepage capture ponds may not achieve full containment.²⁹⁶

Metal leaching is perhaps an even larger problem than acid rock drainage,²⁹⁷ and increased metal concentrations in aquatic environments can negatively influence salmon and the resources on which they depend. Copper and other heavy metals can contaminate fish due to both direct exposure and to contamination of their food resources.²⁹⁸ While copper is essential to living organisms, even a minute increase in copper availability or exposure can be highly toxic to salmon at extremely low levels. It can be acutely toxic at just a few parts per billion, and chronic effects can occur if fish are exposed to an increase of copper in the parts per trillion range.²⁹⁹ A two to eight parts per billion increase of copper can negatively impact a salmon’s olfactory sense, making it difficult for the fish to find mates or return to their spawning grounds.³⁰⁰ Olfactory effects of even brief copper exposure reduces salmon ability to evade predators, and renders them significantly less likely to survive once attacked – with a disproportionate impact on copper-exposed salmon as compared to copper-exposed predators.³⁰¹ Exposure to elevated levels of copper can reduce salmon viability, increase susceptibility to infections, and increase mortality.³⁰² Effects from copper also include impaired brain functioning, difficulty breathing, and changes in blood chemistry and metabolism.³⁰³ Indeed, the results of a recently published study add to the growing body of literature regarding the impacts of low levels of dissolved copper on salmon, which EPA should address in the Watershed Assessment.³⁰⁴

Environmental impacts can be expected in the Pebble area because, although the “relatively common” water treatment failures would be of “limited duration,”³⁰⁵ the copper concentrations of the Pre-Tertiary waste rock so significantly surpass medial lethal concentration values that *even less than a day* of emissions of untreated leachate could kill fish. If improperly

³⁰⁵ EPA Assessment, Vol. 1, 6-38.

collected, this leachate could render the entire Upper Talarik Creek and a large mixing zone of Iliamna Lake toxic to fish and invertebrates.³⁰⁶

Several other metals present at the Pebble deposits can also be environmentally harmful, and are on EPA's list of priority pollutants, including antimony, arsenic, chromium, lead, nickel, selenium, and zinc.³⁰⁷ Dissolved aluminum, for example, can precipitate and form mucus that clogs fish gills.³⁰⁸ Yellow boy, formed when previously soluble iron precipitates as iron hydroxide,³⁰⁹ causes oxygen removal, acidification, and depletion of the water's buffering capacity.³¹⁰ Some interactions among metals (like copper and zinc) can also produce synergistic and antagonistic effects, further damaging the ecosystem.³¹¹ Because zinc is not present in sufficient quantity in the Pebble deposit to economically justify recovery,³¹² "most of it would remain in the tailings and waste rock, accessible to leaching with residual copper."³¹³

C. Mining in Bristol Bay Raises a Risk of Catastrophic Damage

Mining in Bristol Bay presents a real risk of catastrophic failure, and subsequent devastation. The Watershed Assessment – and the history books – are replete with examples of mines-turned-environmental calamities in ways that were unanticipated and beyond the predictions of engineering models or government permits. The unknowns surrounding the Pebble Mine are countless — and acute. Risks relating to the area's geology, the lack of human experience with tailings dams of the magnitude proposed for Pebble,³¹⁴ or with the long-term behavior of engineered storage systems,³¹⁵ for example, are hazards that simply cannot be justified or overlooked.

1. Failure of a Tailings Dam Would Irreversibly Devastate the Bristol Bay Environment

After ore is removed from a deposit, it is ground up and mixed with water and chemicals before the copper, gold, and other metals are separated out. The tailings are stored in perpetuity within large impoundments.³¹⁶ Because the Pebble deposits are low-grade (the metal to ore ratio is low), mining in the area will only be economical if conducted over a large area, producing a large amount of waste.³¹⁷ PLP initially proposed to extract 2.5 billion tons of ore from the Pebble

³¹⁷ EPA Assessment, Vol. 1, ES-10.

deposits, which would require two tailings ponds with five total dams,³¹⁸ but later announced that the deposit contains nearly 11 billion tons of ore.³¹⁹ Since mines are commonly expanded *after* operations begin, it is probable that PLP will seek to extract much more than the initial 2.5 billion ton estimate from Pebble Mine – and more perhaps even than the latest, much larger estimate.³²⁰ If fully mined, the Pebble deposit could process more than 10 billion tons of ore, making it the largest mine of its type in North America. Nonetheless, EPA cautiously estimated the maximum mine scenario at 6.5 billion tons.³²¹ Whatever the volume of ore mined, over 99% of it will be waste material to be stored in tailings facilities forever.³²²

Tailings management is often considered the “most significant environmental challenge associated with mining projects.”³²³ Tailings impoundment dams fail at about ten times the rate of water retention dams,³²⁴ and the rate of failure has actually increased in recent years.³²⁵ Many of the dams that fail are relatively young (5-20 years old), and have been built in the “modern age” of engineering.³²⁶ Since the 1970s, tailings dam failures in the United States have caused a cumulative volume of 10 to 179 million gallons of spillage every year.³²⁷ Yet under present federal and state regulatory practices, there is no existing funding for a dam failure cleanup. The bond required for mines does not cover a dam failure, and “funding to fix a dam after failure and for cleanup would need to be secured either through litigation of a responsible party, or through taxpayer support.”³²⁸

EPA places the annual probability of failure at 1 in 1 million years for “state-of-the-art” mines, and 1 in 10,000 for standard mines. Multiple dams – a feature of both EPA scenarios and the Pebble Mine 2006 water rights application³²⁹ – increase the probability to a recurrence frequency of 3,000 to 300,000 years.³³⁰ Furthermore, two structural features specific to the proposed Pebble Mine, in addition to the area’s geological features described below, could render failure significantly more likely. Analyses of tailings dam failure relative to dam height show that around 56% have occurred in dams over 15 m, with 22% of incidents in dams higher than 30 m.³³¹ The Pebble Mine proposal envisions three dams of *over 200 m* in height.³³²

³³² *Id.* The EPA model assumed three to eight dams, with a possibility of one or more reaching 208 m. EPA Assessment, Vol. 1, ES-15.

Second, very high impoundments and those that contain large volumes of water³³³ – both required to mine the Pebble deposit – are particularly likely to fail if, also like Pebble, they are constructed upstream.³³⁴ Moreover, even if a containment dam remains relatively stable, the facility can still fail from an environmental perspective; dams can generate significant amounts of dust and impact groundwater quality due to seepage.³³⁵

A breach of a tailings dam would unquestionably and irreversibly ravage the Bristol Bay environment through several waves of impacts. The initial flood wave and toxic run, moving at up to 6.1 m/s,³³⁶ would obliterate biota in its path, overtaking and altering the channel and floodplain landscape.³³⁷ The downstream area would be buried in meters of fine-grain sediment, leaving aquatic habitat and biota devastated.³³⁸ Finally, a silt plume would smother benthic organisms, followed by long-term metal oxidization that would release acid and heavy metals.³³⁹

The EPA report analyzes the impacts of two tailings dam size failures at TSF 1 in which a conservative 20% of impounded tailings would be mobilized. The first scenario considers a partially full dam of 98 m and 227-million m³ tailings volume, and the second (after approximately 25 years) at full volume of 208 m and tailings of 1,492 million m³.³⁴⁰ Immediately following a failure of either magnitude, suitable spawning and rearing habitat for salmon and other native fish would be completely eliminated in the North Fork Koktuli River downstream of the tailings dam.³⁴¹ A partial-volume failure would send discharge surging at a more than 1,000-fold increase in magnitude compared to a record flood; full volume failure would result in a 6,500-fold increase.³⁴² EPA conservatively estimates that partial dam failure runout would reach 30 km to the mainstem Koktuli River, and, at full volume, runout would extend 307 km to the currently pristine waters of Bristol Bay.³⁴³ Suitable salmon habitat in the North Fork Koktuli mainstem would be completely lost for the first ten years after failure, followed by decades of very low-quality spawning and rearing habitat.³⁴⁴ These projections reflect uncertainty only with respect to potential *underestimations* of downstream habitat impacts and true salmon abundance,³⁴⁵ because the projections assume only a 20% failure. As discussed more fully in Section VI.D.4 below, these projections are overly cautious: if failure occurs it will likely release more than 20% of the tailings and runout distance will extend significantly farther. The failure scenarios are therefore conservative in that they consistently underestimate the maximum level of impact that could be expected in a worst-case failure scenario. As a result, the Assessment understates the impacts from a worst-case failure.

Even understated, these impacts would be devastating. The damage from a dam failure would constitute “a near-complete loss” of the mainstem North Fork Kookstui fish populations for multiple salmon life cycles. It would affect even the salmon that are at sea during the failure, because they would lose spawning and rearing habitat to which to return.³⁴⁶ Furthermore, tailings persist in streams as sources of metal exposures for decades, and even centuries, causing severe toxic effects and toxic dietary risks to organisms.³⁴⁷ In fact, “the effects of tailings deposition in streams and floodplains persist for as long as they have been monitored at analogous sites.”³⁴⁸ Dilution of toxicity would take an especially long time in Bristol Bay because the relatively undisturbed nature of the watershed means that background levels of total suspended solids are low.³⁴⁹ And remediation raises its own set of concerns. Despite net benefits, it would create long-term impacts on aquatic habitat, particularly because new roads would be required to transport equipment and tailings through the currently roadless Bristol Bay environment.³⁵⁰

2. Location-Specific Risk Factors Increase the Likelihood of a Pebble Mine Structure Failure

Dam failures can be triggered by such events as high rains, hurricanes, rapid snow melt or ice accumulation.³⁵¹ Impoundments are also susceptible to erosion and landslides,³⁵² and – in the Pebble area in particular – permafrost and earthquakes. First, the proposed dams would lie within a zone of sporadic permafrost.³⁵³ Permafrost can cause underground movement, which may pose major problems for tailings impoundments.³⁵⁴

Second, dams in the Pebble area would face a particularly serious threat from earthquakes. The proposed Pebble Mine is located 125 miles from the Alaska Aleutian megathrust,³⁵⁵ which has been responsible for several of the largest earthquakes ever recorded, including the 1964 Prince William Sound earthquake (magnitude 9.2) and the Aleutian earthquake (magnitude 9.1). Earthquakes can have far reaching impacts: in 2002, the 7.9 Denali earthquake ruptured surfaces over 200 miles away, and caused shocks 2,000 miles away.³⁵⁶ Seismic mapping of the Pebble area is incomplete, and there is evidence that the nearest fault may be from only sixteen³⁵⁷ to less than five miles from the mine.³⁵⁸ The proposed Pebble Mine

tailings facilities were designed in 2006 to withstand a 7.8 earthquake 18 miles from the fault.³⁵⁹ The energy from a “floating earthquake” of the same magnitude at 5 km under the site would be significantly greater,³⁶⁰ and if an earthquake occurred five miles away, the force at the mine site would be three times greater than the structures were intended to support.³⁶¹

Earthquakes can cause dam failures via several mechanisms. Outright dam collapse due to shaking or dam overflow from a landslide can occur.³⁶² Earthquakes can also cause static liquefaction, a process by which soil loses its strength and is rendered fluid-like, seriously damaging or causing the collapse of structures built upon it.³⁶³ Earthquakes can also cause subsidence near underground mine workings,³⁶⁴ risking collapse or leakage. And the cumulative effects of smaller earthquakes can lead to problems over time.³⁶⁵

D. EPA’s Deliberately Conservative Assessment Underestimates or Excludes Additional Larger Impacts of Mining to the Ecology of the Region

EPA has presented a judiciously conservative assessment that underestimates the environmental impacts associated with mining the Pebble deposit. Limiting its analysis to direct effects on salmon and salmon-mediated impacts, with a clear delineation of inevitable and possible harm, EPA’s analysis starkly reveals that even a best-case mining scenario would trigger unacceptable impacts on the Bristol Bay environment. And yet, this conservative analysis omits or understates much of the *most severe harm* that a mine would cause.

1. The Proposed Port Presents a Significant Threat to Endangered Cook Inlet Beluga Whales

In addition to the pit, block caving, and tailings storage facilities, a Pebble Mine would require a range of other structures that will disrupt the natural environment of Bristol Bay. The proposed Pebble Mine and EPA mine scenarios call for construction of a port in Cook Inlet’s Iniskin Bay – which would devastate a distinct stock of a highly endangered and geographically isolated species of beluga whales living in Cook Inlet.³⁶⁶ PLP has proposed to build a permanent deepwater port at Iniskin Bay to serve as a product load-out facility and to facilitate in-bound fuel, equipment, and supply shipments.³⁶⁷ According to the 2011 Wardrop report, the port facility would be designed to accommodate shipping of at least 1.1 million tons of concentrate

per year in 28 vessels, as well as 50 million gallons of fuel and 31 container barges per year.³⁶⁸ Energy requirements for the proposed Pebble Mine would be met with a 378-megawatt natural gas-fired turbine at the mine site, as well as an 8-megawatt natural gas-fired generation plant at the port site.³⁶⁹ PLP plans to transport liquefied natural gas from the Kenai Peninsula and across Cook Inlet to the port site via a 60-mile sea-bottom pipeline, and then to the mine site via a 104-mile pipeline buried along a road corridor. A 104-mile road corridor (consisting of 86 miles of new road and 18 miles of existing road) would be constructed to connect the mine site to the port.³⁷⁰ Four pipelines would be constructed between the mine site and the port to transport slurry, diesel fuel, and natural gas.³⁷¹ The road and pipelines alone are estimated to disturb approximately 12.5 square miles.³⁷²

The Cook Inlet beluga whale is the smallest population of beluga whales currently recognized in Alaska and is a genetically distinct and geographically isolated population that lives only in Cook Inlet.³⁷³ In recent years, the population has plummeted from approximately 1,300 to 284 whales.³⁷⁴ The National Marine Fisheries Service (“NMFS”) predicts that beluga whales have a 26% chance of extinction within 100 years and a 70% chance of extinction within 300 years.³⁷⁵ If the current population of beluga whales disappears, it is “highly unlikely” that other belugas would repopulate Cook Inlet.³⁷⁶

NMFS has taken various actions over the past decade in an attempt to halt the decline, but the effort has not been successful. NMFS listed Cook Inlet beluga whales as endangered under the Endangered Species Act in 2008 and designated critical habitat in 2011.³⁷⁷ NMFS designated more than 3,000 square nautical miles of Cook Inlet “critical” to the species’ survival, including much of Iniskin Bay.³⁷⁸ Despite these protections, however, the belugas’ numbers have continued to decline. The 2011 stock assessment found a 20 percent decline since 2010 alone.

Pebble Mine would threaten the whales in several ways. First, the dredging necessary to create the port in Cook Inlet has the potential to re-suspend contaminants in the water; and dredging elsewhere has “seriously impacted” other populations of belugas.³⁷⁹ Second, the port will cause higher traffic in the area, leading to increased water pollution and contaminants, vessel traffic, and noise. In addition to the increased risk to belugas of ship strikes associated with significantly increased vessel traffic, the noise generated by this increase – resulting both from engine noise and cavitation around the propeller – is a particular threat.

³⁷⁹ National Marine Fisheries Service, Conservation Plan, supra note 375, at 55.

Like all marine mammals, Cook Inlet beluga whales depend on sound for vital life functions – such as to navigate, find food, locate mates, avoid predators, and communicate with one another. Artificial man-made noise introduced into their environment can disturb beluga whales and interfere with these important biological behaviors. NMFS has found that anthropogenic noise may impact the survival – and recovery – of the species.³⁸⁰ For example, beluga whales have been observed reacting to ice breaking ships at distances of over 80 km, the effects of which have lasted more than two days following the event.³⁸¹ The inevitable increase in both ambient noise and acute exposure to noise associated with port construction and operation associated with the proposed Pebble Mine would pose a serious risk to this already endangered population.³⁸²

The risk from noise will only increase as ports expand, ship traffic increases, and development moves into previously undisturbed sites in Cook Inlet, including Iniskin Bay, the proposed Knik Arm Bridge and the Port of Anchorage Redevelopment Project. For a small, geographically isolated population of cetaceans, any limitations on range could endanger the animals' recovery. As NMFS correctly observed, “[d]estruction and modification of habitat may result in ‘effective mortalities’ by reducing carrying capacity of fitness for individual whales, with the same consequence to the population survival as direct mortalities.”³⁸³ This risk is further exacerbated by other development activities in Cook Inlet, including oil and gas exploration, coastal development, construction, toxic contaminants, noise disturbance, military operations, competition with fisheries for prey, habitat modifications, waste discharges, urban runoff and climate change. The cumulative impact of these activities on Cook Inlet beluga whales is significant – and potentially deadly.

2. The Secondary Impacts Associated with Mining the Pebble Deposits are Likely Even Greater than the Direct Environmental Harms

The impacts discussed in EPA’s Watershed Assessment relate directly to a large-scale mine in the Pebble area. However, if the Pebble Mine – or any mine – is built in the Bristol Bay watershed, it would inevitably attract additional mining and industrial development and, in turn, even larger impacts to the region. Though EPA purposefully did not incorporate secondary development effects into its Assessment,³⁸⁴ it acknowledged that new infrastructure would facilitate “ancillary development of the landscape, change in the pattern of human habitation, resource extraction, [and] land and water use,” *and that these are likely the most significant of*

³⁸⁰ 73 Fed. Reg. 63919, 62922 (Oct. 22, 2008) (“noise...may have some impact on this population...”); 74 Fed. Reg. 63080, 63087 (Dec. 2, 2009) (“Anthropogenic noise above ambient levels may cause behavioral reactions in whales (harassment) or mask communication between these animals...[noise] would be expected to have consequences to this DPS in terms of survival and recovery.”); NMFS, Conservation Plan at 5 (“This Conservation Plan reviews and assesses the known and possible threats influencing Cook Inlet beluga whales...Potential human impacts include subsistence harvest, poaching, fishing, pollution, *vessel traffic*, tourism and whale watching, coastal development, *noise*, oil and gas activities, and scientific research.”) (emphasis added).

³⁸¹ *Id.* at 58-59.

³⁸² *Id.* at 58.

³⁸³ 72 Fed. Reg. 19854, 19858 (Apr. 20, 2007).

³⁸⁴ EPA Assessment, Vol. 1, 7-15.

impacts for Bristol Bay.³⁸⁵ The environmental impact of ensuing development “can dwarf by orders of magnitude” the direct local effects of the initial infrastructure.³⁸⁶

First, it is fairly standard practice for the mining industry to secure a permit for a smaller mine and then later request permits for expansion.³⁸⁷ NDM’s original plan was to extract 2.5 billion tons of ore, but PLP announced in 2010 that the Pebble deposit contains almost 11 billion tons of mineral resources.³⁸⁸ It is therefore reasonably foreseeable, and indeed virtually inevitable, that the mine will expand far beyond the initial 2.5 billion tons. EPA estimates a minimum of 2 billion tons and maximum of 6.5 billion tons, which is also significantly smaller than the total resource estimate.³⁸⁹ Next, once the mine is built – introducing critical infrastructure for development – it will open the region for industrial scale mining even beyond Pebble.³⁹⁰ In evaluating environmental impacts, the development of a new road is “often only the first step toward industrial or commercial development of the landscape in general, including the proliferation of additional roads.”³⁹¹ The initial infrastructure facilitates and “subsidizes” additional large-scale development, most notably when the initial road connects to a possible trade hub, such as a deepwater port.³⁹²

It is no secret that interest in Bristol Bay industrialization extends beyond the Pebble Mine. The Wardrop report describes several “high priority” exploration targets outside the Pebble deposit.³⁹³ Each additional facility would increase the likelihood of collection and treatment failures and, as a result, the frequency of untreated leachate discharges and incremental impact on the Nushagak and Kvichak watersheds³⁹⁴ – and the chance of long-term adverse downstream effects.³⁹⁵

Furthermore, the Bristol Bay Area Plan lays out a network of roads and highways in the Bristol Bay region, including “regional transportation corridors” that would connect Cook Inlet to the area of the Pebble prospect, as well as King Salmon, Naknek, Egegik, and Port Heiden, and to Chignik and Perryville on the southern Alaska Peninsula. This is in addition to the Plan’s “community transportation projects,” which would create extensions, improvements, or new roads within or adjacent to the Bristol Bay watershed (Chigniks Road Intertie, King Cove-Cold Bay Connection, Newhalen River Bridge, Iliamna-Nondalton Road Intertie, and Naknek-South Naknek Bridge and Intertie), and three potential trans-peninsula transportation corridors.³⁹⁶ Longer roads and pipelines, and the corresponding increase in aquatic area crossings, would increase the probability of each of the mine risks described above, such as culvert failures and pipeline breaks, further damaging the aquatic systems.³⁹⁷

A final impact that the Assessment excludes, but which is “likely to be more significant” than the analyzed salmon-mediated effects, are the mine’s impacts on Alaska Native cultures.³⁹⁸ Dramatic impacts on the traditional culture will result from a shift to a market economy, as well as increased access to the area.³⁹⁹

3. The Impacts of Climate Change Will Increase the Risks Associated with Mining in Bristol Bay

EPA’s Assessment of the potential environmental impacts of mining in Bristol Bay excludes consideration of the added uncertainty and risk associated with future climate change. This is a significant omission. The data reveal that climate change in the region is a large concern, as substantial changes in temperature have taken place over the last 50 years. Annual average temperatures have increased by 3-5°F, and winter temperatures by 6-9°F.⁴⁰⁰ Scientific modeling predicts an increase in frost-free days throughout south-central and south-east Alaska over the next century.⁴⁰¹

Though predictions of the impacts of climate change on the Bristol Bay watershed are inevitably imprecise, models of a watershed to the east of Bristol Bay anticipate sizeable change by the year 2090. These include dramatic increases in average annual evapotranspiration, decreases in snow pack, 43-640% increases in winter streamflows, and 7-73% reductions in summer streamflow.⁴⁰²

As detailed below, failure to consider the effects of climate change in the Bristol Bay watershed underestimates the risk of mining in three areas: (1) the stability of tailings impoundments and other infrastructure, (2) potential flows of contaminants away from the mining site during both catastrophic and non-catastrophic releases, and (3) the stressing and forcing of change on surface and ground water – and resulting effects on ecosystems.

Without an evaluation of the effects of regional climate change on these and all aspects of long-term mining development, the Assessment underestimates the full extent of potential risk. For example, changes in evapotranspiration, precipitation, and runoff will modify plant cover, erosion, flow regimes, flooding and sediment transport. This will in turn affect ecosystem function and carrying capacity. Changes in freshwater delivery, nutrients and sediments may also have profound effects on Bristol Bay itself.⁴⁰³ These long-term increased risks are important to consider since, once constructed, a mine would exist — and need to withstand the demands of a changing climate — for centuries.

⁴⁰² Id.

⁴⁰³ Id.

4. Potential Effects of a Tailings Dam Failure Are Significantly Greater than EPA Estimates

As an initial matter, EPA underestimates the amount of tailings. The Assessment uses a 6.5 billion ton maximum mine scenario, which is considerably smaller than the over 10 billion ton resource estimate described in the 2011 Wardrop report.⁴⁰⁴ In addition, EPA has based its analysis of tailings dam failure risk on four assumptions, each of which leads to significant underestimations of the effects that a failure would have on the Bristol Bay environment. As described in detail in the comments prepared by Professor Johnnie N. Moore, Ph.D., the Watershed Assessment underestimates the amount of tailings potentially released during failure, the run-out distance of these tailings, their immediate and long-term physical and geochemical effects, the duration of toxicity, and impacts associated with climate change.⁴⁰⁵

First, the Watershed Assessment evaluates two failure scenarios, a “partial-volume failure” (227 million m³ tailings volume) and “full-volume failure” (1489 million m³ tailings volume), based on an assumption that a maximum of 20% of total volume of tailings would be released from the impoundment. The seminal study of the relationship between total amount of tailings stored and the amount released, however, predicts, based on a strong regression relationship, a much higher value of 38%.⁴⁰⁶ EPA acknowledged that the 20% figure is low (“[b]ased on historical tailings dam failure data, it is reasonable to assume ... from 30 to 66% of the impoundment tailings material could contribute to debris flow...”⁴⁰⁷), but – consistent with its overarching conservative approach to this Assessment – chose a value “less than measured historical release volumes.”⁴⁰⁸ As Moore explains, 20% is an arbitrarily low value, more typical of much smaller tailings impoundments, and does not accurately reflect the likely effects of a tailings dam failure at Bristol Bay.⁴⁰⁹

Next, run-out from a tailings dam failure in the Pebble area would extend much farther than EPA assumptions predict. EPA conservatively estimates that partial dam failure run-out would reach 30 km to the mainstem Koktuli River, and tailings from a full volume failure would extend 307 km to the waters of Bristol Bay.⁴¹⁰ But again, calculations drawn from a leading study of historical impoundment failure data suggest significantly larger run-out distances of 150-300 km for EPA’s partial failure scenario, and from 450-1000 km at full volume – still *assuming only a 20% tailings release*. When the more likely 38% rate is analyzed, run-out jumps to 460 km and 1800 km for partial and full releases, respectively.⁴¹¹ Under any of these

⁴⁰⁸ Id.

⁴⁰⁹ Moore Assessment of Report EPA 910-R-12-004a, supra note 400, at 3.

⁴¹⁰ EPA Assessment, Vol. 1, 4-57. The partial dam 30 km run-out represents a modeling limitation, not a true assessment of the potential reach of the tailings (“We did not extend the analysis beyond the 30-km reach of the North Fork Koktuli River near its confluence with the South Fork Koktuli River”). EPA’s report also uses a value of 35 km, but this appears to be a typographical error. Id. at Vol. 1, 4-57.

⁴¹¹ Moore, Assessment of Report EPA 910-R-12-004a, supra note 400, at 4.

scenarios, “a spill would likely deposit a large amount of contaminated material into Bristol Bay as well as in the floodplain along all streams leading from the tailings site to Bristol Bay.”⁴¹²

A scientific study specific to the proposed Pebble Mine is consistent with Moore’s analysis, finding that a failure of a tailings dam could lead to the release of billions of tons of mine waste and hundreds of billions of gallons of contaminated water.⁴¹³ Depending on which dam failed, even a modest “lower than expected” failure could have “extraordinary” run-out distances, and reach 270 km to Bristol Bay itself.⁴¹⁴ This run-out distance is an estimate based only on the original 2.5 billion tons mining proposal – an amount much less than the mine may actually produce.⁴¹⁵

Third, although EPA recognizes in its Watershed Assessment that an impoundment failure would deposit large amounts of material on the floodplain, it does not estimate the likely aerial coverage and thickness that would result from such an event – or calculate the duration of toxicity. Based on a review of the literature and historical impoundment failures, it is likely that a tailings dam release “would lead to complete burial of extensive areas of the immediate floodplain between the tailings and Bristol Bay.”⁴¹⁶ Deposition of sediment can alter fundamental biological and physical processes and river function, and tailings are especially damaging because they are enriched in toxic reactive metals.⁴¹⁷ Furthermore, these metal-rich wastes can remain for hundreds to thousands of years, “pos[ing] a continuing hazard to human and ecosystem health.”⁴¹⁸

Finally, climate change should be an important consideration in assessing the stability of tailings structure and other infrastructure, as well as transport flow of contaminants in the event of a release.⁴¹⁹ Hydraulic modeling in a watershed to the east of Bristol Bay predicts substantial change to runoff. South-central Alaska has been designated as a region of disproportionate changes in “heavy” and “very heavy” precipitation, and annual average temperatures in the region are also on the rise.⁴²⁰ The potential impacts that these changes could have on mine structure and rates of failure were not, however, included in EPA’s Assessment – and represent yet another example of EPA’s conservative underestimation of the risks associated with mining in Bristol Bay.

E. Likely Mining Consequences Not Addressed in the EPA Assessment Would Produce Additional Adverse Impacts

1. Subsidence Caused by the Block Caving Will Change Water Flow and Decrease Fishery Productivity

Precise details of the Pebble Mine design have not yet been disclosed, but block caving has been proposed for the Pebble East deposit.⁴²¹ Though sometimes thought to be less environmentally damaging than open pit mining, large-scale underground mining can cause “catastrophic” impacts to overlying material and cause wide-ranging ecosystem effects.⁴²²

Underground mining operations are particularly prone to subsidence. Under EPA’s analysis, a block caving method in the Pebble east side deposit would initially occupy a smaller surface area than the maximum mine site, but subsidence would ultimately increase the footprint.⁴²³ In block caving, subsidence and collapse are encouraged: a series of tunnels are dug under a deposit, forcing the collapse of overlying substrate.⁴²⁴ As ore falls and is subsequently removed, the material in higher levels will crack, which can lead to large surface subsidence.⁴²⁵ Most hard-rock deposits contain faults and intrusions, hydrothermal alteration of rocks, and many clays and clay-like minerals, all of which reduce rock strength and make subsidence more likely.⁴²⁶ Finally, water is removed from mine sites in order to facilitate the mining process — further weakening the surrounding area.⁴²⁷

Subsidence can have large impacts on surface and ground water⁴²⁸ and can cause them both to be redirected.⁴²⁹ The overlying strata is fractured – often to the surface – allowing contact between water and the mineralized material not removed by mining.⁴³⁰ Subsidence also leads to increased acid production and transportation from the mine.⁴³¹ Both the redirection of water flow and the increase of acid can have large impacts on local fisheries.

It is unlikely that subsidence can be mitigated. Mining companies have not managed to successfully reclaim or re-vegetate subsidence areas surrounding a block cave mine, and one researcher concluded that “[n]o evidence was found that subsidence effects at underground hardrock mines using block caving can be managed or mitigated short of not mining.”⁴³² Subsidence is therefore an issue that should be included in the final Watershed Assessment.

2. Fugitive Dust Generated by the Mine Will Degrade Aquatic Habitats, Damaging Fisheries

The proposed Pebble Mine would negatively impact the ecology of the region through the generation of fugitive dust. Fugitive dust can be blown from many mine surfaces, including the mine itself, access roads, and tailings ponds, and can also be generated by moving and storing mine materials.⁴³³ One study predicted “conservatively” that fugitive dust would impact over 33 square miles surrounding the mine, but commented that the effects could be much wider.⁴³⁴ Within the area impacted by the mine are 33 miles of ephemeral, intermittent, and perennial streams, including ten miles of anadromous waters designated by the Alaska Department of Fish and Game.⁴³⁵ Over the life of the mine, this area would be “significantly degraded,” and the dust would impact both streams and vegetation.⁴³⁶ Impacts caused by fugitive dust can be long-lasting, and ecosystems may be slow to recover.⁴³⁷

When fugitive dust is generated, it covers surrounding vegetation, causing increased mortality in plants. This can result in devegetation of large areas surrounding the mine, including areas that support salmon.⁴³⁸ When vegetation is lost, surface runoff increases, which in turn leads to increased stream turbidity and sedimentation. Fugitive dust can also settle in water and smother both salmon eggs and organisms that serve as food for salmon.⁴³⁹ Furthermore, fugitive dust can transport heavy metals into the surrounding water, air, and soil. This can be especially problematic in an area that is also exposed to acid mine drainage — which increases the bioavailability of copper⁴⁴⁰ and harms sensitive salmon.

As the mine ages, copper from fugitive dust could affect benthic invertebrates, including mayflies, caddis flies, and stoneflies.⁴⁴¹ Such impacts to these populations would be “crucial” and most likely “long term.”⁴⁴² These species are important food resources for salmon and other fish, so declines in these populations will negatively impact salmon species. Furthermore, copper could accumulate to concentrations that would cause acute or chronic effects in salmon directly.⁴⁴³ As one study found: “a certainty exists that, even with mitigation measures employed at the mine, copper and other metals will likely be mobilized in runoff or leached into the surface and/or groundwater” over the life of the mine.⁴⁴⁴ Given the potential impacts of fugitive dust, the final Assessment should address this issue.

VII. EPA ACTED WITHIN ITS AUTHORITY TO ISSUE THE WATERSHED ASSESSMENT AND MAY USE ITS FINDINGS TO INITIATE 404(C) PROCEEDINGS

A. EPA's Section 104 Authority to Prepare and Publish Reports on Water Pollution Has Never Been Challenged and Is Clearly Supported By Legislative History

Section 104 of the Clean Water Act authorizes the EPA Administrator, in broad terms, to use the tools of research and investigation to prevent, reduce and eliminate pollution of the nation's waters. Among the specific actions authorized, the Administrator may conduct "research, investigations. . . surveys, and studies related to the causes, effects, extent, prevention, reduction, and elimination of pollution."⁴⁴⁵ The Administrator is also authorized to "collect and make available, through publications and other appropriate means, the results of and other information, including appropriate recommendations by him in connection therewith," pertaining to the agency's investigations, surveys, and studies.⁴⁴⁶ This broad investigative power is an essential corollary to EPA's section 404(c) authority. It enables the Agency to collect relevant data and disseminate its findings, so that any section 404(c) action is grounded in science and the public interest.

The Bristol Bay Watershed Assessment clearly falls within the type of "investigations" and "studies" contemplated by the statute. During House Debates on the Clean Water Act Amendments of 1972, one of the bill's architects, Rep. John Blatnik, stated that section 104's purpose, in combination with other subsections, is to "[i]ncrease the level of research, [e]liminate chance, [p]rovide the basis for calculation," and help agencies "proceed in an informed and responsible manner."⁴⁴⁷ During the same debates, the Chairman of the Senate Public Works Committee affirmed that section 104 was intended, among other things, to authorize studies that "consider the effects of exploitation of mineral resources and fossil fuels" on water ecosystems, including fishing, recreation, and "other beneficial purposes."⁴⁴⁸ The Watershed Assessment is thus the type of scientific document intended by the bill's authors. It presents a factual and scientific analysis of the watershed that investigates the causes and effects of mining. The Assessment has no regulatory force, but is used to enable "informed and responsible" agency decision-making.

In the past, EPA has not cited its section 104 authority when preparing and issuing scientific assessments, perhaps because this authority has been considered so uncontroversial. However the agency has, without challenge, published several documents similar to the Watershed Assessment. For example:

- In 2002, EPA published an "ecological risk assessment" regarding the environmental impacts of human activities in the Waquoit Bay watershed in Massachusetts.⁴⁴⁹

⁴⁴⁵ 33 U.S.C. § 1254(a)(1).

⁴⁴⁶ 33 U.S.C. § 1254(b)(1).

⁴⁴⁷ House Debate on H.R. 11896 Before The Committee of the Whole House, 92nd Cong. 355 (1972) (Statement of John Blatnik, Chair of the House Committee on Public Works).

⁴⁴⁸ Id. at 572.

⁴⁴⁹ U.S. EPA, Waquoit Bay Watershed Ecological Risk Assessment: The effect of land-derived nitrogen loads

- In 2008, the agency published a report predicting the future introduction and spread of non-indigenous species in the Great Lakes,⁴⁵⁰ conducting a comprehensive scientific assessment of an area covering roughly 94,000 square miles.⁴⁵¹ Critics of the Watershed Assessment have argued that EPA could not possibly have thoroughly surveyed the Bristol Bay watershed, an area roughly 24,000 square miles, however EPA has already successfully conducted a similar assessment of an area more than three times the size.
- In 2009, the agency published a report on the effect of mountaintop mining and valley fills on the aquatic ecosystems of Central Appalachia.⁴⁵² While the conclusions of the report were challenged by coal industry supporters, a random sample of roughly 100 comments – of the nearly 800 comments submitted critical of the report – found none contesting EPA’s authority to prepare and issue the report.

EPA’s Bristol Bay Watershed Assessment is clearly authorized by section 104 of the Clean Water Act, as evidenced by the statutory language and the record of congressional intent. When EPA has issued similar reports in the past, it has done so without controversy regarding its statutory authority. By citing to section 104 now, EPA has simply identified the explicit congressional authority on which its action is based – authority that the agency has for decades used to issue scientific assessments and on which it properly relies here.

B. Objections to EPA’s Watershed Assessment Process Are Unfounded

1. Data Quality Act

Northern Dynasty Minerals has suggested that EPA’s Assessment has been undertaken in violation of the Data Quality Act.⁴⁵³ What argument they intend to offer in support of this claim is unclear as none is available.

The Data Quality Act (“DQA”), better known as the Information Quality Act (“IQA”), is a short and simple piece of legislation with no legislative history that merely provides “policy and procedural guidance to Federal agencies for ensuring and maximizing the quality, objectivity, utility, and integrity of information.”⁴⁵⁴ Notably – and conclusively – it creates no

private right of action.⁴⁵⁵ Instead, it tasks the *agency* with developing an administrative mechanism for dealing with information quality challenges. Any dispute as to the quality of the information in the EPA Assessment would therefore need to follow the administrative mechanisms created by EPA to receive and address such challenges.⁴⁵⁶

The only threshold requirement that EPA must (and unquestionably did) meet in releasing the Watershed Assessment is to satisfy the three “quality” criteria of objectivity, utility, and integrity of the information.⁴⁵⁷ First, a presumption of objectivity exists for information subject to peer-review⁴⁵⁸ – a process that the draft Assessment will undergo in just a couple of weeks.⁴⁵⁹ Second, the Assessment will be “useful” in determining the form of future management and development within the Bristol Bay watershed,⁴⁶⁰ thereby satisfying the utility requirement.⁴⁶¹ Finally, EPA has protected the “integrity” of the Assessment because it has prevented the unauthorized alteration and destruction of the information contained therein,⁴⁶² and thus the final “quality” criteria has been satisfied.

⁴⁵⁵ Family Farm Alliance v. Salazar, 749 F.Supp.2d 1083, 1090 (E.D.Cal. 2010); Salt Inst. v. Thompson, 345 F.Supp.2d 589, 601 (E.D.Va. 2004), *aff’d sub nom. on alternate grounds*, Salt Inst. v. Leavitt, 440 F.3d 156 (4th Cir. 2006). The disclaimer in the EPA Guidelines also reminds readers that the guidelines “provide non-binding policy and procedural guidance, and are therefore not intended to create legal rights, impose legally binding requirements or obligations on EPA or the public when applied in particular situations.” U.S. EPA, EPA/260-02-008, Guidelines for Ensuring and Maximizing the Quality, Objectivity, Utility, and Integrity, of Information Disseminated by the Environmental Protection Agency (“EPA Guidelines”) (2002).

⁴⁵⁶ Consolidated Appropriations Act § 515(b)(2); Guidelines for Ensuring and Maximizing the Quality, Objectivity, Utility, and Integrity of Information Disseminated by Federal Agencies, 67 Fed. Reg. 8458 (February 22, 2002); *see Family Farm Alliance*, 749 F.Supp.2d at 1089. According to the EPA Guidelines, an affected person should first contact the EPA informally to resolve any questions about information quality before submitting a formal Request for Correction (“RFC”) to the agency. EPA Guidelines. If the requestor is dissatisfied with EPA’s response to the RFC, then she can submit a Request for Reconsideration (“RFR”). *Id.*

⁴⁵⁷ 67 Fed. Reg. at 8459 (“‘Quality’ is an encompassing term comprising utility, objectivity, and integrity. Therefore, the guidelines sometimes refer to these four statutory terms, collectively, as ‘quality.’”).

⁴⁵⁸ *Id.*

⁴⁵⁹ *See* An Assessment of Potential Mining Impacts on Salmon Ecosystems of Bristol Bay, Alaska—Peer Review Panel Members and Charge Questions, 77 Fed. Reg. 33213 (June 5, 2012). Even in the absence of this presumption of objectivity for peer-reviewed information, the Assessment satisfies the two-pronged “objectivity” test because (1) the draft publication is available to the public, (including being subject to the technical peer review process), which ensures that the information is both transparent and reproducible; and (2) the Assessment is based on accurate, reliable, and unbiased information, derived from sound statistical and research methods. *See* 67 Fed. Reg. 8459; U.S. EPA, EPA 910-R-12-004a-c, An Assessment of Potential Mining Impacts on Salmon Ecosystems of Bristol Bay, Alaska (2012).

EPA employs corresponding System & Information Integrity

2. Due Process

Northern Dynasty has also publicly questioned the Watershed Assessment as a potential deprivation of its Due Process rights.⁴⁶³ Again, the basis for this claim is difficult to discern, as no viable challenge exists. To establish a procedural due process claim, a litigant must prove 1) a protectable liberty or property interest, and 2) a denial of adequate procedural protections.⁴⁶⁴ Even if PLP could assert a protectable liberty or property interest – which it cannot – the relevant EPA procedures have adequate protections in place to overcome this challenge.

PLP statements thus far seem to point to a claim that the release of the Watershed Assessment and/or potential subsequent EPA 404(c) action will deprive the Partnership of a due process right to proceed to the EIS stage of environmental review. Due process doctrine and precedents do not sustain such a claim. Liberty doctrine does not offer any analogues for PLP's use here.⁴⁶⁵ Nor can PLP assert any protectable property interest. Unlike a property interest in an "ongoing commercial enterprise,"⁴⁶⁶ an undeveloped project that must someday survive permitting and environmental review (indeed, neither "ongoing" nor as yet an "enterprise") is not protectable. A state-created benefit or entitlement cannot logically arise from something to which PLP is not yet entitled; it cannot legally arise from a regulation authorizing administrative discretion.⁴⁶⁷ By analogy, in reviewing whether compensation is required when government action prohibits certain land uses, the Supreme Court explained:

[T]he owner of a lakebed [] would not be entitled to compensation when he is denied the requisite permit to engage in a landfilling operation that would have the effect of flooding others' land. Nor the corporate owner of a nuclear

measures (documents listed on pages 29 to 30 of the NIST Guide) to ensure information integrity, pursuant to non-public internal agency guidance documents. Telephone Interview with Vipul Bhatt, Information Security Officer, EPA Office of Information Analysis and Access (July 10, 2012).

⁴⁶³ Northern Dynasty Comments at Public Hearings on EPA's Draft Bristol Bay Watershed Assessment Report (May 18, 2012), available at

<http://www.northerndynastyminerals.com/ndm/NewsReleases.asp?ReportID=526103& Type=News-Releases& Title=Northern-Dynasty-comments-on-the-EPAs-draft-Bristol-Bay-Watershed-Assessmen>.

⁴⁶⁴ *Foss v. Nat'l Marine Fisheries Serv.*, 161 F.3d 584, 588 (9th Cir. 1998).

⁴⁶⁵ Courts have found protected liberties to include, for example, the freedom from bodily restraint, as well as the right to contract, engage in common occupations of life, acquire useful knowledge, marry, establish a home and raise children, and worship. *Bd. of Regents of State Colleges v. Roth*, 408 U.S. 564, 572 (1972) (quoting *Meyer v. Nebraska*, 262 U.S. 390, 399 (1923)). In the procedural due process context, liberty has been defined as "those privileges long recognized . . . as essential to the orderly pursuit of happiness by free men." *Id.* Permitting review of an as-yet unapproved project falls far afield these core rights. Indeed, liberty cases generally focus on incomparable situations such as protections for inmates, see, e.g., *Sandin v. Connor*, 515 U.S. 472 (1995), and public school students, see, e.g., *Ingraham v. Wright*, 430 U.S. 651 (1977). The most analogous alleged liberty interest has been claimed in the preservation of access to natural areas. *Sierra Ass'n. For Env't v. Fed. Energy Regulatory Comm'n*, 744 F.2d, 661, 665 (9th Cir. 1984). In light of the significant environmental impacts that a mine in Bristol Bay would cause, Northern Dynasty is far more likely to infringe such a liberty than be denied it. Furthermore, the asserted natural area liberty interest remains uncertain as the *Sierra* court did not need to evaluate the merits of the liberty interest because, as here, the existing regulatory framework contained sufficient due process protections. *Id.*

⁴⁶⁶ *Marathon Oil Co. v. U.S. Env'tl. Protection Agency*, 564 F.2d 1253, 1275 (9th Cir. 1977) (Wallace, J., dissenting) (citing *Louis K. Liggett Co. v. Baldridge*, 278 U.S. 105, 111 (1928)).

⁴⁶⁷ *Bd. of Regents of State Colleges v. Roth*, 408 U.S. 564, 577 (1972).

generating plant, when it is directed to remove all improvements from its land upon discovery that the plant sits astride an earthquake fault.⁴⁶⁸

Without a protectable liberty or property interest, no claim of inadequate protections can be made.⁴⁶⁹

However, even if PLP were to meet the first threshold, it fails in the second. A court may not impose additional process protections when, as here, the procedural thresholds of the Administrative Procedure Act (“APA”) have been cleared.⁴⁷⁰ Both the section 104 Watershed Assessment and the process for section 404(c) action include substantial notice and public comment opportunities to safeguard any protectable interest.⁴⁷¹ EPA has held eight noticed⁴⁷² public hearings for the Watershed Assessment⁴⁷³ and will subject its draft Assessment to peer review.⁴⁷⁴ The 404(c) process includes similar notice and public comment requirements.⁴⁷⁵ Even where a first proceeding is essentially dispositive of a second – not true of the Watershed Assessment’s relationship to a 404(c) determination – and the first proceeding contains *no* procedural safeguards at all, if procedural protections are in place for the second, no due process violation has occurred.⁴⁷⁶ EPA conduct thus far and its procedures for future action are therefore in full compliance with the APA,⁴⁷⁷ and a claim of deprivation of due process must fail.

3. Peer Review Charge

Although they cite no legal authority, PLP and NDM have both vigorously attacked EPA’s draft charge to peer reviewers of the Watershed Assessment.⁴⁷⁸ Their principal criticism has been that the draft charge—a set of questions intended to guide peer review of the

⁴⁶⁸ Lucas v. S.C. Coastal Council, 505 U.S. 1003, 1029 (1992). The Supreme Court went on to note that compensation is not required even where “regulatory action may well have the effect of eliminating the land’s only economically productive use but it does not proscribe a productive use that was previously permissible under relevant property and nuisance principles.” *Id.* Therefore, even if regulatory action would effectively “kill” an economic use of land, that practical reality does not alter or heighten the due process requirements.

⁴⁶⁹ Morrissey v. Brewer, 408 U.S. 471, 481 (1972).

⁴⁷⁰ Vermont Yankee Nuclear Power Corp. v. NRDC, 435 U.S. 519, 523-24 (1978). Even in processes found lacking, the remedy does not bar a given agency action (here the Watershed Assessment or a section 404(c) veto), but simply requires sufficient notice and opportunity for public comment. See W. Oil & Gas Ass’n v. U.S. Env’tl Protection Agency, 633 F.2d 803, 813 (9th Cir. 1980).

⁴⁷¹ The EIS process also has sufficient due process, but need not be evaluated here as PLP appears to assert deprivation *of* an EIS, not *by* an EIS.

⁴⁷² See, e.g., <https://www.federalregister.gov/articles/2012/06/05/2012-13431/an-assessment-of-potential-mining-impacts-on-salmon-ecosystems-of-bristol-bay-alaska-peer-review>.

⁴⁷⁸ Statement of Ronald W. Thiessen, President & CEO, Northern Dynasty Minerals Ltd. Docket # EPA-HQ-ORD-2012-0358 (June 26, 2012), available at <http://regulations.gov> (search docket number, then search within results for “Northern Dynasty”).

assessment—has a “narrow focus.”⁴⁷⁹ They allege that this focus “prohibits” reviewers from performing a more comprehensive critique of the assessment.⁴⁸⁰ This concern is specious.

First, OMB and EPA guidelines state that draft charge questions should serve to collect “informed comment on *identified specific issues [in order] to properly focus*” the peer review panel’s work, while also permitting a more global evaluation of the report’s methodology, scope, assumptions and conclusions.⁴⁸¹ EPA’s draft charge does both, asking a series of targeted questions and concluding by inviting reviewers to provide “any other comments concerning the assessment, which have not already been addressed by the charge questions.”⁴⁸² This question – which did not appear in the draft charge, but was included in the final peer review questions – certainly resolves the objection of an overly-narrow charge. It was, however, an unnecessary addition because a general evaluation of methodology, scope, and validity by the peer reviewers is assumed—indeed, required. According to EPA guidelines, peer reviewers *must* assess these aspects of the report, and they will do so in this case.⁴⁸³ Judging the soundness and validity of the report is the core of the panel’s task, and nothing in EPA’s draft charge limits its ability to do so.⁴⁸⁴

Beyond this generalized and unsupported claim, NDM’s most prominent objections in its comment are that: 1) the Watershed Assessment failed to sufficiently incorporate the 27,000-page PLP-funded Environmental Baseline Document⁴⁸⁵; 2) EPA’s draft charge questions do not invite the peer reviewers to highlight the “positive effects of mineral development”⁴⁸⁶; and 3) the Watershed Assessment’s assumptions regarding mine failure and other pollution scenarios were overly pessimistic, omitting due credit to industry best practices.⁴⁸⁷ These critiques suggest that NDM/PLP would prefer a very different scientific assessment and review process. The report would make liberal use of non-peer-reviewed data provided by NDM/PLP; its risk analysis section would rely on the most optimistic assumptions about mining impacts; and the draft charge would present leading questions that implicitly undermine the validity of the Watershed Assessment, while focusing instead on the positive impacts of mineral development on salmon ecosystems.⁴⁸⁸ None of these steps is warranted by the applicable EPA guidelines or regulations,

⁴⁸⁸ For example, NDM clearly misunderstands the role of the Draft Charge when it suggests EPA ask such blatantly leading questions as: “Was the rationale for excluding seven of the nine watersheds in Bristol Bay from analysis based on sound scientific logic, or was the rationale based on a pre-conceived conclusion regarding the impacts of

nor would they serve the public or improve the Assessment itself. They would merely serve to present a slanted and misleading picture of potential mining impacts in the Bristol Bay area.

B. Environmental Baseline Document

In fact, EPA included findings from the PLP-funded EBD in the Watershed Assessment. Nonetheless, PLP has criticized EPA for not fully incorporating the EBD into the agency's scientific literature review – something that PLP, by its own delay and inaction, prevented EPA from doing. Its suggestion now that EPA somehow intentionally excluded PLP and its closely-held, self-serving, and non peer-reviewed input is disingenuous.

In February 2011, EPA announced its plans to prepare the Watershed Assessment, soliciting input from the scientific community, tribes, local and state agencies, as well as the public and industry.⁴⁸⁹ At that time, EPA announced its plan to complete the review within six to nine months, setting a clear timeline for stakeholders to provide relevant materials for review.⁴⁹⁰ Although research for the EBD was effectively complete by 2008, Pebble inexplicably failed to make the EBD public until February 2012, a year after EPA's call for materials and only three months before the draft Watershed Assessment was finalized—too late for the authors to thoroughly review and incorporate 27,000 pages of new documentation.⁴⁹¹

In addition – and unlike the Watershed Assessment itself – the EBD has not been subject to peer review, nor has its underlying data been made readily accessible in a timely and accessible manner for public review and analysis. Without reliable peer-review of the EBD, provided to EPA in a reasonable timeframe applicable to all stakeholders, the agency could not fairly be expected to rely on it – or to delay release of its draft Assessment until PLP decides, after at least four years of refusing access to its data and analysis, to release them.

VIII. BASED ON THE WATERSHED ASSESSMENT, EPA SHOULD EXERCISE ITS AUTHORITY UNDER SECTION 404(C) AND PROHIBIT THE SPECIFICATION OF THE PEBBLE MINE AREA AS A DISPOSAL SITE FOR DREDGED AND FILL MATERIAL

The EPA Assessment, its record, and the best available science provide a compelling and legally sufficient factual basis for EPA to find that “unacceptable adverse effects” within the

mining in general,” and “Given that the Assessment did not follow EPA's own ecological risk assessment guidelines or the data quality guidelines, that inappropriate data and site specific data known to the authors were not used in the Assessment, and that many of the assumptions and conclusions are not documented or based on an appropriate scientific review of the appropriate information, do you believe that the authors' conclusions in this Assessment represent good scientific practice?” Statement of Ronald W. Thiessen, *supra* note 478.

⁴⁹¹ Press Release: Pebble Partnership Releases Environmental Baseline Document (Feb. 15, 2012), available at <http://www.northerndynastyminerals.com/ndm/NewsReleases.asp?ReportID=507084>.

meaning of section 404(c) will occur in the Bristol Bay watershed as a result of development of the Pebble deposit.⁴⁹² Significant degradation is likely – even inevitable. EPA is therefore well within its authority to proceed with 404(c) action after an expeditious review of public comments and peer review, even in the absence of any formal mine application.

A. EPA’s Authority Under the Clean Water Act

Section 404(c) of the Clean Water Act gives EPA the explicit authority to prohibit, deny, or restrict permitting by the U.S. Army Corps of Engineers’ (“Army Corps”) of dredge and fill projects when EPA finds that the discharge “will have an unacceptable adverse effect on municipal water supplies, shellfish beds and fishery areas (including spawning and breeding areas), wildlife, or recreational areas.”⁴⁹³

The purpose and meaning of this authority must be understood and applied in light of the goals of the Clean Water Act as a whole.⁴⁹⁴ The purpose of the Clean Water Act is “to restore and maintain the chemical, physical, and biological integrity of the Nation’s waters.”⁴⁹⁵ To that end, Congress made it “the national goal that the discharge of pollutants into the navigable waters be eliminated”⁴⁹⁶ Significantly, the statute also provides that “it is the national goal that wherever attainable, an interim goal of water which provides for the protection and propagation of *fish, shellfish, and wildlife and provides for recreation in and on the water* be achieved”⁴⁹⁷

With these words, Congress established a national aim of protecting water and the fish, shellfish, wildlife and water-based recreation that it provides – the very resources that section 404(c) was enacted to protect. Other Clean Water Act provisions, too, focus on that language, indicating that Congress considered protection of those enumerated resources to be especially important.⁴⁹⁸ Thus, the Clean Water Act sets two clear goals: eliminating water pollution and preserving the ecological functions of our nation’s waterways, with a particular emphasis on protecting fish, shellfish, and wildlife.

EPA’s mandate pursuant to 404(c) to consider specific impacts on the environment and the appropriate timing to do so are evident in the provision’s text:

The Administrator is authorized to prohibit the specification (including the withdrawal of specification) of any defined area as a disposal site, and he is authorized to deny or restrict the use of any defined area for specification (including the withdrawal of specification) as a disposal site, whenever he determines, after notice and opportunity for public hearings, that the discharge of

⁴⁹² As discussed above, the effects outside the watershed would also cause adverse effects, which would be potentially more devastating than the direct harm.

⁴⁹³ 33 U.S.C. § 1344.

⁴⁹⁴ *Samantar v. Yousuf*, 130 S.Ct. 2278, 2289 (2010) (quoting *United States v. Morton*, 467 U.S. 822, 828 (1984)).

⁴⁹⁵ 33 U.S.C § 1251(a).

⁴⁹⁶ *Id.* § 1251(a)(1).

⁴⁹⁷ *Id.* § 1251(a)(2) (emphasis added).

⁴⁹⁸ *See, e.g., id.* §§ 1326(a), 1330(a) & 1343(c).

such materials into such area will have an unacceptable adverse effect on municipal water supplies, shellfish beds and fishery areas (including spawning and breeding areas), wildlife, or recreational areas. Before making such determination, the Administrator shall consult with the Secretary. The Administrator shall set forth in writing and make public his findings and his reasons for making any determination under this subsection.⁴⁹⁹

Supported by this language and the case law applying it, EPA has correctly interpreted this provision to mean that (1) its discretion is limited to consideration of a number of specifically-enumerated environmental factors; and (2) the agency is authorized to act proactively even before the commencement of the Army Corps's section 404 permitting process.⁵⁰⁰

B. The Discharges Associated with the Pebble Mine Would Violate the Section 404(b)(1) Guidelines and, as a Consequence, Section 404(c)

EPA may act pursuant to section 404(c) if a future discharge is *reasonably likely* to cause “an unacceptable adverse effect on municipal water supplies, shellfish beds and fishery areas (including spawning and breeding areas), wildlife, or recreational areas.”⁵⁰¹ The agency has explained that “absolute certainty is *not* required. Because 404(c) determinations are by their nature based on predictions of future impacts, what is required is a reasonable likelihood that unacceptable adverse effects will occur — not absolute certainty but more than mere guesswork.”⁵⁰² Indeed, as one court succinctly described, “[EPA’s] authority to veto to protect the environment is practically unadorned.”⁵⁰³ The agency’s use of that authority is informed, however, by regulations governing the Army Corps’ permitting of discharges of dredge and fill material.⁵⁰⁴

EPA’s rules governing section 404(c) provide that “[i]n evaluating the unacceptability of such impacts, consideration should be given to the relevant portions of the section 404(b)(1) guidelines (40 CFR part 230).”⁵⁰⁵ Although the Army Corps is responsible for implementing those guidelines during the permitting process, as EPA explained when it published its 404(c) regulations, “[w]hile Congress had faith in the Corps’ administrative experience, it recognized EPA as the ‘environmental conscience’ of the Clean Water Act.”⁵⁰⁶ These guidelines define

⁴⁹⁹ 33 U.S.C. § 1344(c) (emphasis added).

⁵⁰⁰ A reviewing court will defer to an agency’s reasonable interpretation of a statute it is charged with administering unless the statutory provision in question is unambiguous. Chevron, U.S.A., Inc. v. NRDC 467 U.S. 837, 842-43 (1984). See also Mingo Logan Coal Co. v. U.S. Env’tl. Protection Agency, CA No. 10-0541 (ABJ) (D.D.C. Mar. 23, 2012), at 22 (“The record expressly states that EPA’s 404(c) authority will be exercised prior to the issuance of a permit, and it also reflects the Conferees’ understanding that EPA’s responsibilities were to be limited to those specifically assigned.”).

⁵⁰¹ 33 U.S.C. § 1344(c).

⁵⁰² Denial or Restriction of Disposal Sites; Section 404(c) Procedures, 44 Fed. Reg. 58076, 58078 (Oct. 9, 1979) (emphasis added).

⁵⁰³ James City Cnty v. U.S. Env’tl. Protection Agency, 12 F.3d 1330, 1336 (4th Cir. 1993).

⁵⁰⁴ 40 C.F.R. § 231.2(e).

⁵⁰⁵ 40 C.F.R. § 231.2(e).

⁵⁰⁶ Denial or Restriction of Disposal Sites; Section 404(c) Procedures, 44 Fed. Reg. 58081.

“unacceptable adverse effect” as an “impact on an aquatic or wetland ecosystem which is likely to result in significant degradation of municipal water supplies (including surface or ground water) or significant loss of or damage to fisheries, shellfishing, or wildlife habitat or recreation areas.”⁵⁰⁷

In considering whether to issue a permit, the Army Corps is permitted to consider the wide array of factors found in those guidelines, both environmental and non-environmental.⁵⁰⁸ By contrast, in deciding whether to exercise its authority under section 404(c), EPA may consider *only* the portions of those rules relevant to evaluating adverse effects on the section 404(c) resources. EPA has found the following 404(b)(1) guidelines relevant to its 404(c) analysis:

- Significant degradation of waters of the United States (40 C.F.R. § 230.10(c))⁵⁰⁹
- Secondary effects (40 C.F.R. § 230.11(h))⁵¹⁰
- Cumulative effects (40 C.F.R. § 230.11(g))⁵¹¹

The proposed Pebble Mine – or as EPA’s Assessment reveals, any large-scale mine in the area – would implicate each of these criteria and result in “unacceptable adverse effects” on the fisheries, wildlife, municipal water supply, and recreation in the Nushagak and Kvichak drainages within the meaning of section 404(c).

1. The Pebble Mine Would Cause Significant Degradation of the Waters of the United States, which Supports a Finding of Unacceptability Under Section 404(c)

The section 404(b)(1) guidelines provide that no discharge of dredged or fill material shall be permitted if the discharge will cause or contribute to significant degradation of waters of the United States.⁵¹² The guidelines state that impacts leading to “significant degradation” include:

⁵⁰⁷ 40 C.F.R. § 231.2(e).

⁵⁰⁸ James City Cnty., 12 F.3d at 1335 (“Congress obviously intended the Corps of Engineers in the initial permitting process to consider the total range of factors bearing on the necessity or desirability of building a dam in the Nation’s waters, including whether the project was in the public interest.”).

⁵⁰⁹ Spruce No. 1 Mine Veto, Final Determination of the U.S. Environmental Protection Agency Pursuant to § 404(c) of the Clean Water Act Concerning the Spruce No 1 Mine, Logan County, West Virginia (Jan. 13, 2011) at 45, (hereinafter “Spruce Mine Veto”), available at http://water.epa.gov/lawsregs/guidance/cwa/dredgdis/upload/Spruce_No_1_Mine_Final_Determination_011311_sig_ned.pdf, rev’d on other grounds, Mingo Logan Coal Co. v. U.S. Evtl. Protection Agency, CA No. 10-0541 (ABJ) (D.D.C. Mar. 23, 2012), appeal docketed, No. 12-5150 (D.C. Cir. July 18, 2012).

⁵¹⁰ See, e.g., id. at 83 (“The adverse secondary effects discussed . . . include substantial changes in aquatic communities, such as loss of fish and salamander diversity and sensitive mayfly and stonefly taxa, as well as shifts to more pollution-tolerant taxa.”).

⁵¹¹ See, e.g., Everglades (Rem, Becker & Senior Corp.) Veto, 53 Fed. Reg. 30,093-094 (Aug. 10, 1988) (veto based in part on cumulative impacts as described at 52 Fed. Reg. 38,519 (Oct. 16, 1987)); see also Jack Maybank Veto, 50 Fed. Reg. 20,291 (May 15, 1985) (veto based in part on cumulative impacts to the area, including functional losses in the St. Helena Sound ecosystem, as described at 49 Fed. Reg. 30,112, 30,114 (July 26, 1984)); Sweedon Swamp Veto, 51 Fed. Reg. 22,977, 22,978 (June 24, 1986).

⁵¹² 40 C.F.R. § 230.10(c).

- Significantly adverse effects of the discharge of pollutants on *life stages of aquatic life* and other *wildlife* dependent on aquatic ecosystems;
- Significantly adverse effects of the discharge of pollutants on *aquatic ecosystem diversity, productivity, and stability*;
- Significantly adverse effects of the discharge of pollutants on *human health or welfare*, including but not limited to effects on *municipal water supplies, fish, and wildlife*.⁵¹³

An element of each of those specific determinations is a consideration of the “[p]ossible loss of environmental values.”⁵¹⁴ The guidelines also provide that in evaluating these three categories of harm, EPA should engage a range of more specific factual determinations, including how the proposed discharge would impact the “physical substrate” of the water body,⁵¹⁵ “[w]ater circulation, fluctuation, and salinity,”⁵¹⁶ turbidity,⁵¹⁷ contaminant levels,⁵¹⁸ and the “aquatic ecosystem and organisms.”⁵¹⁹ Furthermore, EPA should consider not only the direct impacts of the disposal of dredge and fill material into the disposal site, but also the secondary impacts on the surrounding landscape.⁵²⁰ In other words, EPA must take a broad view of the environment when it evaluates the impacts associated with a potential discharge. The Watershed Assessment accomplishes precisely these goals, and finds that mining would lead to significant degradation.

⁵¹³ *Id.* (emphasis added).

⁵¹⁴ *Id.* § 230.11(a)-(e).

⁵¹⁵ *Id.* § 230.11(a) (“Determine the nature and degree of effect that the proposed discharge will have, individually and cumulatively, on the characteristics of the substrate at the proposed disposal site.”).

⁵¹⁶ *Id.* § 230.11(b) (“Determine the nature and degree of effect that the proposed discharge will have individually and cumulatively on water, current patterns, circulation including downstream flows, and normal water fluctuation. Consideration shall be given to water chemistry, salinity, clarity, color, odor, taste, dissolved gas levels, temperature, nutrients, and eutrophication plus other appropriate characteristics.”).

⁵¹⁷ *Id.* § 230.11(c) (“Determine the nature and degree of effect that the proposed discharge will have, individually and cumulatively, in terms of potential changes in the kinds and concentrations of suspended particulate/turbidity in the vicinity of the disposal site.”).

⁵¹⁸ *Id.* § 230.11(d) (“Determine the degree to which the material proposed for discharge will introduce, relocate, or increase contaminants.”).

⁵¹⁹ *Id.* § 230.11(e) (“Determine the nature and degree of effect that the proposed discharge will have, both individually and cumulatively, on the structure and function of the aquatic ecosystem and organisms. Consideration shall be given to the effect at the proposed disposal site of potential changes in substrate characteristics and elevation, water or substrate chemistry, nutrients, currents, circulation, fluctuation, and salinity, on the recolonization and existence of indigenous aquatic organisms or communities.”).

⁵²⁰ According to the section 404(b)(1) guidelines:

- (1) Secondary effects are effects on an aquatic ecosystem that are associated with a discharge of dredged or fill materials, but do not result from the actual placement of the dredged or fill material. Information about secondary effects on aquatic ecosystems shall be considered prior to the time final section 404 action is taken by permitting authorities.
- (2) Some examples of secondary effects on an aquatic ecosystem are fluctuating water levels in an impoundment and downstream associated with the operation of a dam, septic tank leaching and surface runoff from residential or commercial developments on fill, and leachate and runoff from a sanitary landfill located in waters of the U.S. Activities to be conducted on fast land created by the discharge of dredged or fill material in waters of the United States may have secondary impacts within those waters which should be considered in evaluating the impact of creating those fast lands.

Id. § 230.11(h).

a. Significant Adverse Effects on the Life Stages of Aquatic Life and Other Wildlife Dependent Species

The combined effects of inevitable habitat loss and reduced streamflow, and likely acid mine drainage of high levels of copper and other contaminants, will disrupt the life cycles of the aquatic species and the terrestrial wildlife that depend on them. Bristol Bay provides one of the world's largest runs of sockeye salmon and Alaska's largest run of Chinook salmon. Both species are critically important to the health and survival of other species in the region, and both species are particularly sensitive to the kinds of impacts associated with large-scale metallic sulfide mining generally – and Pebble Mine specifically. Moreover, because of its proposed location at the headwater streams of the Nushagak and Kvichak drainages, the project presents an especially acute threat. Those streams are important spawning grounds for the region's salmon. Reduced flow downstream would impact all life stages, including the migration of adults, the viability of eggs, the emergence of fry, and the timing of smolt migration. As discussed in detail above, these impacts would reverberate through the ecosystem and disrupt the life stages of a wide variety of other species.

The relationship between salmon and other wildlife in the region is complex and highly evolved. Growth rates, litter size, and reproductive success of a variety of species are determined in part by the robustness of the salmon population. For example, brown bears are larger in the Bristol Bay watershed due to their high-protein salmon-based diets, minks time their reproduction with the availability of salmon, and bald eagles experience greater reproductive success because of these fisheries.⁵²¹

EPA's Watershed Assessment and substantial scientific evidence therefore establish that the effects of large-scale metallic sulfide mining would endanger the life processes of aquatic and terrestrial species in the watershed.

b. Significant Adverse Effects on Aquatic Ecosystem Diversity, Productivity, and Stability

The habitat destruction, reduced water quantity, and compromised water quality associated with a large-scale mining effort in the Pebble region will dramatically impact the aquatic ecosystem's diversity, productivity, and stability. Principally, this will happen by way of harm to the region's salmon populations. Salmon interact with the flora and fauna of the region in myriad distinct and important ways, many of which have been described above. At a more general level, however, salmon are an indispensable species in the watershed's aquatic ecosystems. They are a keystone species and their presence in the watershed is essential to maintaining the structure and character of the ecosystem.⁵²² The loss of salmon will severely diminish ecosystem "diversity, productivity and stability."⁵²³

⁵²¹ Willson & Halupka, Keystone Species, *supra* note 217, at 493; The Nature Conservancy of Alaska, Ecoregional Assessment, *supra* note 6, at 75, 103.

⁵²² Hauser, Potential Impacts, *supra* note 78, at 5.

⁵²³ 40 C.F.R § 230.10(c).

The sheer magnitude of the proposed mine and the vulnerability of a keystone species place the Bristol Bay aquatic ecosystem at a high risk of significant adverse effects.

c. Significant Adverse Effects on Human Health or Welfare

It is appropriate to consider the effects of the proposed Pebble Mine on human health to the extent that the effects are tied to one of the section 404(c) factors. Here, human health and welfare are inextricably tied to the availability of a productive salmon fishery and healthy wildlife in and around Bristol Bay; a negative impact on salmon quality or quantity “would certainly” negatively impact these salmon-based cultures.⁵²⁴ “Salmon as subsistence food and as the basis for Alaska Native cultures are inseparable.”⁵²⁵ This connection between the people, the fish, and the wildlife of the Bristol Bay region and the threat to it posed by the Pebble Mine is not only relevant to a determination under section 404(c), but it implicates the federal government’s trust responsibilities⁵²⁶ and raises significant environmental justice concerns.

The six villages that first petitioned EPA all depend on a subsistence lifestyle. Nondalton gathers an average of 358 pounds of subsistence per person in the village each year. New Stuyahok gathers 700 pounds per person, Levelock gathers 884 pounds per person, Ekwook gathers 797 pounds per person, Curyung (Dillingham) gathers 242 pounds per person, and Koliganek gathers 830 pounds per person.⁵²⁷ All but one of these villages gathers substantially more subsistence than the area’s average of 300 pounds per person.⁵²⁸ No alternative food sources are economically viable to these communities. “Continued access to high-quality subsistence resources” is therefore “necessary for survival of the Alaska Natives and other local residents.”⁵²⁹ Furthermore, each of these villages has its traditional subsistence area close to the location of the mine or in the Nushagak watershed area. The Kuktuli River, whose tributaries

⁵²⁴ EPA Assessment, Vol. 1, 5-76. Elements of the Alaska Native cultures that are interrelated with subsistence resources include nutrition and physical health, mental and emotional health, language, extended family relationships, strong social networks surrounding food sharing, and economic viability. *Id.*

⁵²⁵ *Id.* at Vol. 1, 2-19.

⁵²⁶ The requested relief is consistent with the federal government’s trust responsibility to protect Native American tribes. In *Seminole Nation v. United States*, for example, the Court observed that “[the federal government’s] conduct, as disclosed in the acts of those who represent it in dealings with the Indians, should therefore be judged by the most exacting fiduciary standards.” 316 U.S. 286, 297 (1942). All agencies of the federal government are bound by this obligation to consider the Native Americans’ best interests in their decisions and actions, including EPA. See, e.g., *Nance v. U.S. Env’tl. Protection Agency*, 645 F.2d 701, 711 (9th Cir. 1981) (“It is fairly clear that any Federal government action is subject to the United States’ fiduciary responsibilities toward the Indian tribes.... As a result of the letters from the Undersecretary of the Interior, and the Crow Tribe, and the failure of EPA to respond to those letters before approving the redesignation, the responsibility to exercise those fiduciary obligations is fairly placed upon the EPA.”) In this case, this fiduciary obligation applies to EPA’s decision whether to protect petitioners’ subsistence fishing and hunting grounds from contamination and degradation caused by the permitting of the proposed Pebble Mine in the heart of the Bristol Bay watershed. See also Exec. Order No. 12,898, 59 Fed. Reg. 7,632-33 (Feb. 11, 1994) (“To the greatest extent practicable and permitted by law . . . , each Federal agency shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations in the United States”).

⁵²⁷ Duffield et al., *Economics of Wild Salmon Watersheds*, *supra* note 9, at 11.

⁵²⁸ *Id.*

⁵²⁹ EPA Assessment, Vol. 1, 2-19.

will be used to store the tailings, feeds into Nushagak River and is part of its watershed.⁵³⁰ Thus, contamination of the Koktuli River may affect all of the villagers who fish in the Nushagak watershed.

Under these circumstances, EPA can properly find that the adverse environmental effects of the Pebble Mine will significantly jeopardize human health and welfare.

d. Significant Adverse Effects on Municipal Water Supply

EPA defines municipal water supplies for purposes of 404(c) as “including surface or ground water.”⁵³¹ As described above, extensive connectivity exists between ground and surface water in Bristol Bay. Largely due to this connectivity, ground and surface water would suffer unacceptable adverse impacts as a result of large-scale mining in the area.

Surface-groundwater connectivity would be severed in many places by the mine site, roads, and pipelines, dramatically degrading the watershed, and the quality of its water. In addition, contaminated water from the mine site would be treated and discharged as a replacement for a portion of the groundwater that would otherwise be feeding stream systems. A “key aspect” of post-closure hydrology is that groundwater flows away from the mine site.⁵³² This replacement water could have substantially different chemical characteristics than the native waters.⁵³³ Because seepage collection systems are “notoriously inefficient (even ineffective) and expensive to operate,” the result could be centuries of downgradient surface water contamination.⁵³⁴ In addition, the Pebble site is below freezing for seven months of the year, and wastewater treatment and discharge would take place during the remaining five-months. This significantly affects the feasibility of successful mine site wastewater treatment because the quantity of water that would need to be treated and discharged during the shortened time window is unprecedented.⁵³⁵

The effects on ground and surface water are especially significant because the total wastewater treatment that will be required for discharges from Pebble Mine’s tailings impoundments, waste rock disposal areas, and mine pit to the region’s water could exceed 26 million gallons per day for Wardrop’s 25-year scenario, and as much as 58.5 million gallons per day (greater than the wastewater treatment capacity of the City of Anchorage) at full-pit underground mine exploitation.⁵³⁶ In order to prevent degradation of surrounding water quality, *all* contaminated mine site wastewater must be captured and treated. But the Pebble site is both

⁵³⁶ Riley & Yocom, Mining the Pebble Deposit, *supra* note 296, at 24.

“highly permeable” and “highly saturated,” and over time, it is likely that contaminated water will “seep through the tailings and enter the highly permeable groundwater system that provides base flow to local streams.”⁵³⁷ Even though tailings are considered to have low permeability, they are likely to migrate over time into the groundwater system and release contaminants to surface waters.⁵³⁸ The “uncommonly porous nature” of the project area “place[s] into serious doubt the ability of a conventional, unlined tailings impoundment to capture toxic tailing leachate before it enters the local groundwater.”⁵³⁹ And tailings dams, once constructed, would exist *forever*. “[G]iven the relatively ephemeral nature of human institutions over these timeframes, we would *expect* that eventually monitoring, maintenance, and treatment would cease,” and the water quality of leachate would from that point on control the area’s water quality.⁵⁴⁰

The “inherent” complexity of the groundwater-surface water interactions “can make regulating or controlling such interactions during large-scale landscape development very difficult.”⁵⁴¹ Attempts to avoid harm or remediate the interconnectivity are therefore likely be futile and adverse impacts severe.

2. The Cumulative Impacts of the Pebble Mine Are Unacceptable Under Section 404(c)

When the agency evaluates the potential effects of a particular project, it must also consider the collective consequences of those impacts, in combination with other past or future discharges. The section 404(b)(1) guidelines require that factual findings “predicted to the extent reasonable and practical” be made regarding cumulative effects on the surrounding landscape, “attributable to the collective effect of a number of individual discharges of dredged or fill material.”⁵⁴² These findings should then be considered in the agency’s determination of whether a particular discharge would result in unacceptable adverse effects on the environment.⁵⁴³ Other projects – proposed or authorized – that might contribute to additional adverse environmental

⁵⁴¹ *Id.* at Vol. 1, 5-45.

⁵⁴² 40 C.F.R. § 230.11(g).

⁵⁴³ The full text of the guidelines describes cumulative impacts as follows:

(1) Cumulative impacts are the changes in an aquatic ecosystem that are attributable to the collective effect of a number of individual discharges of dredged or fill material. Although the impact of a particular discharge may constitute a minor change in itself, the cumulative effect of numerous such piecemeal changes can result in a major impairment of the water resources and interfere with the productivity and water quality of existing aquatic ecosystems.

(2) Cumulative effects attributable to the discharge of dredged or fill material in waters of the United States should be predicted to the extent reasonable and practical. The permitting authority shall collect information and solicit information from other sources about the cumulative impacts on the aquatic ecosystem. This information shall be documented and considered during the decision-making process concerning the evaluation of individual permit applications, the issuance of a General permit, and monitoring and enforcement of existing permits.

Id. § 230.11(g).

effects in the vicinity of where the particular discharge would occur,⁵⁴⁴ as well as past or present projects that may have affected the current baseline conditions of the region,⁵⁴⁵ form part of this analysis.

The cumulative effects of the discharges directly associated with the proposed Pebble Mine – and the additional development that will necessarily accompany large-scale metallic sulfide mining in the region – are significant and adverse. Permitting one mine will inevitably and irrevocably open the region to significant industrial development inconsistent with the sustainable use and conservation of its natural resources. Cumulative environmental impacts may occur from discharges associated with building a power plant to run the Pebble Mine, the roads and culverts over which trucks will travel on their way to Cook Inlet, the pipelines carrying slurry, natural gas, and diesel, and the dredging and infrastructure required to build a deepwater port in the Cook Inlet. In addition, a mine in the area would likely expand as the ore body is developed, causing greater impacts than current projections estimate.

Moreover, as EPA has recognized, “once the infrastructure for one mine is built, it would likely facilitate the development of additional mines.”⁵⁴⁶ In the wake of a permit being issued for Pebble Mine, numerous other mining claims that have already been staked out in this pristine, now-undeveloped region, and whose success or failure depend upon the industrial foundation of a first mine, would resurface. With additional structures and mining projects also comes a heightened likelihood and frequency of failures—from small to catastrophic.⁵⁴⁷ Further, though EPA elected to exclude from its Assessment the effects of secondary development associated with multiple mines, the agency recognized – and should emphasize in a 404(c) deliberation – that their cumulative impacts “would contribute to adverse effects on fish, wildlife, and Alaska Native culture.”⁵⁴⁸

Finally, while EPA was careful to generate a scientific analysis with individual lines of cause and environmental effect, in reality, each of the causation stressors described in these comments occur simultaneously, or in temporal proximity, creating synergistic effects.⁵⁴⁹ With regard to salmon fisheries, each stressor would slowly reduce salmon resilience,⁵⁵⁰ and would act in combination to reduce habitat and food resources, increase metal bioavailability, and reduce

⁵⁴⁴ See, e.g., Spruce Mine Veto, *supra* note 509, at 73 (“EPA considered cumulative effects to the Coal River subbasin . . . and the Headwaters Spruce Fork sub-watershed . . . if the Spruce No. 1 Mine is constructed . . . and other reasonably foreseeable (proposed and/or authorized but not constructed) surface mining projects within the Coal River sub-basin are constructed.”); Jack Maybank Veto, Final Determination of the Assistant Administrator for External Affairs Concerning the Jack Maybank Site on Jehossee Island, South Carolina Pursuant to Section 404(c) of the Clean Water Act (April 5, 1985) at 19, available at <http://water.epa.gov/lawsregs/guidance/wetlands/upload/MaybankFD.pdf> (“Direct wetland loss and associated impacts on fish, shellfish, and wildlife resulting from the proposed project are magnified when considered in the context of previous wetland alteration in the area of the Maybank Site.”).

⁵⁴⁵ *Id.* (“This cumulative effects analysis also takes into consideration the past and present mining projects within the sub-basin and sub-watershed, and the extent to which they have affected the current baseline conditions within the sub-basin and subwatershed.”)

genetic variability and disease resistance.⁵⁵¹ Because salmon are crucial players in ecosystem health, these impacts – magnified by each additional development project facilitated by the Pebble Mine infrastructure – would echo throughout the ecosystem.

C. The Requested Action is Consistent with EPA’s Past Section 404(c) Actions

Initiating 404(c) proceedings here would be consistent with EPA’s past exercise of its section 404(c) authority. The agency has intervened under section 404(c) on thirteen prior occasions,⁵⁵² and except where it acted after the issuance of a final permit by the Army Corps, its intervention has been upheld.⁵⁵³ In this case, the scale and scope of the potential significant adverse impacts of a mine in the Nushagak and Kvishak drainage substantially exceed those threatened by the projects the agency has considered in past 404(c) determinations. Based on the overwhelming evidence in the Watershed Assessment that mining in the pristine Bristol Bay watershed will have devastating and unavoidable consequences, EPA’s intervention under section 404(c) would likely be upheld in this case.

1. The Fisheries Impacts Would Surpass Those EPA Has Addressed in Prior 404(c) Determinations and Warrant a Finding of Unacceptability

Potential impact on fisheries has been an important consideration in EPA’s past actions under section 404(c).⁵⁵⁴ In several cases, the agency has focused on the diversity of fish species affected, recreational fishing considerations, the monetary value of the fishery, and the health of the existing fish populations.⁵⁵⁵ Bristol Bay is one of the last places on earth to produce abundant wild sockeye salmon runs, and the Kvichak River specifically produces more sockeye salmon than any other river in the world.

The salmon of Bristol Bay sustain commercial fisheries that are worth around \$300 million annually, hold significant recreational importance (\$173.1 million annual value), and support Alaska Natives who hunt and fish for their subsistence (\$6.3 million annual subsistence harvest value).⁵⁵⁶ Considering all economic sectors, the Bristol Bay watershed generates nearly \$480 million in one year⁵⁵⁷ – making its value over the life of a mine roughly equivalent to that of the Pebble Mine over the same period.⁵⁵⁸ The key difference is, of course, indefinite

⁵⁵⁵ Id.

⁵⁵⁶ EPA Assessment, Vol. 1, 2-17.

⁵⁵⁷ Id.

⁵⁵⁸ The net present value of Bristol Bay fisheries, assuming a \$480 million yearly value at a 7% discount rate for 25, 45, and 78 years (taking the discount rate and date ranges from the Wardrop Material Change Report) is roughly

sustainability in the case of the fisheries, and irreversible environmental damage and ore exhaustion (plus over \$6 billion in corporate gain⁵⁵⁹) in the case of a mine. Salmon are also central to the cultural heritage of the people who live in the region, and represent an irreplaceable keystone species with a critical role in defining the ecological characteristics of the region.

Never before has EPA had to consider the fate of such a culturally and ecologically important fishery. The special significance of salmon to the Bristol Bay watershed, its people, and its wildlife – and the threat to them all if a mine is permitted – strongly support EPA action in this case.

2. The Size and Scope of the Project Support a Finding of Unacceptability Under Section 404(c)

The sheer size and scope of Pebble Mine surpass any other project EPA has reviewed under section 404(c). One way to compare the proposed Pebble Mine with past cases is by measuring the area of inundated surface directly impacted by the proposed dredge and fill. EPA's minimum and maximum mine sites would eliminate from 55 to 87 miles of stream channel.⁵⁶⁰ Current estimates of the proposed Pebble Mine place it within this range, at approximately 68 linear miles of stream channel elimination.⁵⁶¹ In EPA's final determination in the Spruce Mine case, the agency placed significant weight on the many miles of streams in jeopardy – in that case *just 6.6 miles*.⁵⁶² The Pebble Mine is expected to destroy over *9,200 acres* of habitat, including wetlands, open water areas, and streams.⁵⁶³ EPA estimates this figure at between 8,330 and 20,293 acres.⁵⁶⁴ In other cases, EPA has concluded that the destruction of less than 1,000 acres of inundated wetlands could support a determination of unacceptability.⁵⁶⁵ In other words, the size of the proposed Pebble Mine project is unprecedented in comparison to past section 404(c) proceedings.

A mere calculation of the number of inundated acres affected does not, however, fully capture the scope of what is at stake in the case of Pebble Mine. Not only does such a measure ignore the many cumulative and secondary effects of large-scale mining in the region – detailed at length above – but it ignores the pristine quality and enormous scale of the ecosystem that Pebble Mine would jeopardize. A potential discharge that would so manifestly threaten such an abundance of pristine wilderness is unprecedented.

\$5.59 billion, \$6.12 billion, and \$6.39 billion, respectively. PLP projections for the same date ranges come to \$3.84 billion, \$6.13 billion, and \$6.81 billion, respectively. Wardrop, Preliminary Assessment, *supra* note 61, at 78.

⁵⁶⁴ EPA Assessment, Vol. 1, ES-11.

⁵⁶⁵ See, e.g., Big River Veto, 55 Fed. Reg. 10,666 (Mar. 22, 1990) (575 acres of wetland); Sweedens Swamp Veto, reported at 51 Fed. Reg. 22,977, 22,978 (June 24, 1988) (32 acres of wetland); Jack Maybank Veto, 50 Fed. Reg. 20,291 (May 15, 1985) (900 acres of wetland).

3. The Impacts on Headwater Streams Are Significant and Support a Finding of Unacceptability Under Section 404(c)

In the Spruce Mine proceeding, EPA emphasized that the discharges at issue would have impacted important headwater streams in the region. Just as important as the project's size was the agency's recognition of the important function headwater streams provide in a healthy, functioning ecosystem. Taking note of the science, EPA wrote:

Many studies now point to the role headwater streams play in the transport of water, sediments, organic matter, nutrients, and organisms to downstream environments; their use by organisms for spawning or refugia; and their contribution to regional biodiversity Additionally, destruction or modification of headwater streams has been shown to affect the integrity of downstream waters, in part through changes in hydrology, chemistry and stream biota⁵⁶⁶

At least as devastating as what was proposed at the Spruce Mine in West Virginia, Pebble Mine would appropriate all of the ground and surface waters within the proposed area of the mine, including the headwaters of the North and South Forks of the Koktuli River and the Upper Talarik Creek. Those headwaters would be subject to mine use over the entire life of the mine – severely limiting the extent to which salmon can return to their upstream spawning area and jeopardizing important aquatic and riparian habitats. If EPA carefully considers the effects on headwater streams, it must find that the proposed Pebble Mine poses unacceptable environmental impacts to the Bristol Bay watershed.

D. EPA May Not Engage in Cost-Benefit Analysis to Reach a Decision Under Section 404(c)

Although the mining industry will offer self-interested claims that EPA should consider the potential economic cost of section 404(c) relief – and PLP can be expected to do so here⁵⁶⁷ – those claims have no legitimate legal or factual basis. EPA's power under section 404(c) is at once wide in its discretion and narrowly focused on the environmental priorities of the Clean Water Act. Section 101 prioritizes the goal of protecting fish, shellfish, wildlife and recreation on the water⁵⁶⁸ – and section 404(c) does so, too. By contrast, neither section contains any reference to, or authority for, considering the potential economic impact of approving or disapproving a challenged development – or deciding a request for action under section 404(c). Economic considerations are irrelevant and may not be considered.

⁵⁶⁶ Spruce Mine Veto, *supra* note 509, at 20.

⁵⁶⁷ Indeed, Northern Dynasty's comments to EPA's peer review charge object that "peer reviewers would be forbidden from questioning why the BBWA does not consider any positive effects of mine development, despite the significant socio-economic challenges facing the Bristol Bay region and its rapidly declining Native population." Press Release, Northern Dynasty calls on EPA to substantially expand and extend role of independent experts assembled to review 'Bristol Bay Watershed Assessment' (Jun. 28, 2012).

⁵⁶⁸ City of Alma v. United States, 744 F. Supp. 1546, 1562 (S.D.Ga.1990) ("[T]he CWA grants EPA wide discretion to employ section 404(c) as it deems appropriate.").

The Court of Appeals for the Fourth Circuit has considered the relationship between the Army Corps' role in the section 404 permitting process and EPA's 404(c) authority. Significantly, it concluded that section 404(c) permits EPA to consider the environment at the exclusion of other values.⁵⁶⁹ The Army Corps, on the other hand, must consider an array of factors bearing on the desirability of permitting the construction of a dam – or in issuing any dredge and fill permit under section 404 – including whether the project is in the public interest.⁵⁷⁰ Because EPA's authority to veto is based only on its obligation to protect the environment,⁵⁷¹ the Court of Appeals observed that EPA's authority "is practically unadorned," holding that the agency may rest its decision to intervene under section 404(c) *solely* on a finding of unacceptable adverse effects to the environment.⁵⁷² Without exception, all district courts that have addressed the issue have adopted that same reasonable interpretation of section 404(c).⁵⁷³

The provision's legislative history confirms that Congress intended section 404(c) to serve purely as an environmental check on the Army Corps' permitting authority under section 404. An early House amendment to the bill would have given the Army Corps the power to administer the permitting of dredged or fill material without EPA oversight. Instead, the Army Corp would have been, by itself, "required to determine that the discharge would not unreasonably degrade or endanger human health, welfare, or amenities or the marine environment, ecological systems, or *economic potentialities*."⁵⁷⁴ That scheme for the section 404 permit program did not survive the House and Senate conference committee. According to the conference committee report:

The conferees agree that the Administrator of the Environmental Protection Agency shall have authority to prohibit specification of a site and deny or restrict the use of any site for the disposal of any dredge or fill material which he determines will adversely affect municipal water supplies, shellfish beds and fishery areas (including spawning and breeding areas), wildlife, or recreational areas.⁵⁷⁵

It was this formulation of section 404(c) that made its way into the final version of the bill. The decision to abandon the language of economics and rest the oversight authority with EPA suggests what courts and EPA have always understood: that section 404(c) was intended to fulfill the environmental and ecological priorities of the Clean Water Act.

⁵⁶⁹ James City Cnty. v. U.S. Env'tl. Protection Agency, 12 F.3d 1330, 1336 (4th Cir.1993).

⁵⁷⁰ Id. For a full discussion of public interest considerations, see Wild Salmon Center and Trout Unlimited, Bristol Bay's Wild Salmon Ecosystems and the Pebble Mine: Key Considerations for a Large-Scale Mine Proposal at 41-46.

⁵⁷¹ James City Cnty., 12 F.3d at 1336.

⁵⁷² Id.

⁵⁷³ Id.; see also Creppel v. U.S. Army Corps of Engineers, Civ. A. No. 77-25, 1988 WL 70103 (E.D. La. June 29, 1988). ("The plain language of section 404(c) does not require a balancing of environmental concerns against "the public interest." There is no mention of this kind of 'statutory balancing' . . .").

⁵⁷⁴ Joint Explanatory Statement of the Committee of Conference, Pub. L. No. 92-500 reprinted in 1 Legislative History of the Federal Water Pollution Control Act Amendments of 1972, at 325 (1973) (emphasis added).

⁵⁷⁵ Id.

EPA’s own understanding of its enabling statute is in keeping with the courts’ interpretation. The agency has defined “unacceptable adverse effect” as the “impact on an aquatic or wetland ecosystem which is likely to result in significant degradation of municipal water supplies (including surface or ground water) or significant loss of or damage to fisheries, shellfishing, or wildlife habitat or recreation areas.”⁵⁷⁶ Significantly, in EPA’s statement of purpose that accompanied the rulemaking, the agency explained that “section 404(c) does not require a balancing of environmental benefits against non-environmental costs such as the benefits of the foregone project. This view is based on the language of 404(c) which refers only to environmental factors.”⁵⁷⁷ EPA emphasized that “there is no requirement in 404(c) that a cost/benefit analysis be performed, and there is no suggestion in the legislative history that the word ‘unacceptable’ implies such a balancing.”⁵⁷⁸

Accordingly, any claim by PLP of potential economic hardship if EPA precludes mining through 404(c) action must be rejected.

E. EPA May Invoke its 404(c) Authority Proactively to Prevent Large-Scale Mining in the Nushagak and Kvichak Drainages

EPA is entitled to intervene under section 404(c) before the commencement of the section 404 permit process. Despite protestations by mining enthusiasts, the Agency’s Watershed Assessment is neither factually nor legally “premature.”⁵⁷⁹ There is ample evidence to support proactive action here given the sheer magnitude of the anticipated development in the pristine Nushagak and Kvichak drainages and EPA findings that construction of a mine would result in unavoidable impacts on one of the country’s most outstanding fisheries. In light of all that is understood about the impacts of large-scale mines on landscapes and ecosystems – as well as the sensitivity of the wilderness at stake in Bristol Bay – there is no need to delay 404(c) action once the Assessment comment period and peer review process are complete.

As a matter of law, EPA unquestionably has the power to act proactively under section 404(c). The interpretation of any statute begins with its plain meaning.⁵⁸⁰ By their terms, the first two clauses of section 404(c) provide that “the Administrator is authorized to prohibit the specification (including the withdrawal of specification) of any defined area as a disposal site, and he is authorized to deny or restrict the use of any defined area for specification (including the withdrawal of specification) as a disposal site, *whenever* he determines” the environmental impacts would be unacceptable.⁵⁸¹ This plainly worded passage provides that EPA is free to act

⁵⁷⁶ 40 C.F.R. § 231.2(e).

⁵⁷⁷ Denial or Restriction of Disposal Sites; Section 404(c) procedures, 44 Fed. Reg. 58076, 58078 (Oct. 9, 1979) (“When Congress intended EPA to consider costs under the Clean Water Act, it said so.”).

⁵⁷⁸ *Id.*

⁵⁷⁹ Northern Dynasty Comments at Public Hearing (May 31, 2012). The company’s statement that it “welcomed” the Watershed Assessment when it first learned that EPA had initiated the process is notably schizophrenic. Are we to believe that the process was *not* premature at its start, but is so now, when its findings do not support the corporation’s mining goals?

⁵⁸⁰ *Milner v. Dep’t of Navy*, 131 S.Ct 1259, 1264 (2011), citing *Park ‘N Fly, Inc. v. Dollar Park & Fly, Inc.*, 469 U.S. 189, 194 (1985) (“Statutory construction must begin with the language employed by Congress and the assumption that the ordinary meaning of that language accurately expresses the legislative purpose.”)

⁵⁸¹ 33. U.S.C. § 1344(c) (emphasis added).

proactively, before an area has been specified as a disposal site – “whenever” the Administrator makes the required determinations.⁵⁸² The statute’s application isn’t limited to occasions where a permit application for a specified disposal site has already been filed, since the administrative action may take the form of a prohibition. In contrast to a “withdrawal” or “denial” of a permit or permit application, a prohibition by definition works to preempt the action it forbids, which, in this case, is the issuance of a permit.

This reading of the statute is also consistent both with EPA’s application of it and, on judicial review, with the courts’ interpretation. A review of EPA’s rulemaking and prior section 404(c) practice reveals that EPA long ago rejected Northern Dynasty’s claim that pre-application action is premature. Beginning with the promulgation of the rules governing section 404(c) implementation, the agency stated that it may “prohibit the specification of a site under section 404(c) with regard to any existing or potential disposal site *before a permit application has been submitted to or approved by the Corps or a state.*”⁵⁸³

In response to public comments critical of this rule, the agency first pointed to the plain language of section 404(c), advancing similar textual arguments.⁵⁸⁴ It then directly addressed the rationale for its pre-permit authority, explaining that such authority

will facilitate planning by developers and industry. It will eliminate frustrating situations in which someone spends time and money developing a project for an inappropriate site and learns at an advanced stage that he must start over. In addition, advance prohibition will facilitate comprehensive rather than piecemeal protections of wetlands.⁵⁸⁵

EPA directly rejected comments foreshadowing Northern Dynasty’s current position which argued that “pre-permit actions were inappropriate because it would be impractical to identify unacceptable adverse effects before a specific discharge is proposed.”⁵⁸⁶ The agency responded that “at least in theory, there are instances where a site may be so sensitive and valuable that it is possible to say that any filling of more than X acres will have unacceptable adverse effects.”⁵⁸⁷

⁵⁸² Id.

⁵⁸³ 40 C.F.R. § 231.1(a) (emphasis added).

⁵⁸⁴ Denial or Restriction of Disposal Sites; Section 404(c) Procedures, 44 Fed. Reg. 58076, 58077 (Oct. 9, 1979) (“EPA feels that the statute clearly allows it to use 404(c) before an application is filed.”).

⁵⁸⁵ Id.

⁵⁸⁶ Id. Furthermore, the NEPA process itself requires evaluation of reasonable *and hypothetical* scenarios as part of the EIS analysis of alternatives. 40 C.F.R. §4332(2)(E). The permitting process for a proposed Pebble mine would require PLP to develop an EIS with several reasonable alternatives – hypothetical in nature and different than their proposed discharge. See, e.g., *City of Carmel-By-The-Sea v. United States Dept. of Trans.*, 123 F.3d 1142, 1159 (1997). Evaluation of hypothetical mine scenarios is therefore par for the course in Section 404 permitting.

⁵⁸⁷ Id. Over the course of EPA’s application of section 404(c), the agency has consistently interpreted this statutory provision to permit proactive use. In exercising its veto authority in 1984, for example, the Administrator explained: [w]here the facts warrant it, I may prohibit all future discharges of all dredged or fill material at a site, whether or not the site has previously been specified in a 404 permit. If there is already a permit, my actions would be a ‘withdrawal of specification’; if no permit has been issued, my action would be a ‘prohibition of specification.’

The Bristol Bay watershed is precisely such a place and therefore warrants proactive use of section 404(c) power.

Notable beyond the fact of EPA's section 404(c) authority, however, is the risk that, by failing to act proactively, EPA may be deemed to have exceeded it. In a recent decision of the federal district court in the District of Columbia, the agency's veto of the Spruce No.1 Surface Mine permit was vacated solely on the ground that the subject permit had already been granted by the Army Corps.⁵⁸⁸ Having reviewed the language of the statute, its legislative history, and EPA's implementing regulations, Judge Amy Berman Jackson concluded that "the clear import of the provision, as all the parties agree, is that Congress gave EPA the right to step in and veto the use of certain disposal sites at the start, thereby blocking the issuance of permits for those sites."⁵⁸⁹ The problem in the Spruce case, the court held, was that EPA had waited too long to act:

The Court concludes that EPA exceeded its authority under section 404(c) of the Clean Water Act when it attempted to invalidate an existing permit by withdrawing the specification of certain areas as disposal sites after a permit had been issued by the Corps under section 404(a). Based upon a consideration of the provision in question, the language and structure of the entire statutory scheme, and the legislative history, *the Court concludes that the statute does not give EPA the power to render a permit invalid once it has been issued by the Corps.*⁵⁹⁰

Noting that "the agency has never before invoked its 404(c) powers to review a permit that had been previously duly issued by the Corps,"⁵⁹¹ the court granted summary judgment in favor of the permit holder, concluding that section 404(c) did not authorize EPA to veto a permit once it has been issued.⁵⁹² According to the court, it was "unreasonable to sow a lack of certainty into a system that was expressly intended to provide finality."⁵⁹³ EPA is currently appealing the decision. Whether or not this decision is ultimately upheld on appeal, it clearly reflects the risk of waiting.

Moreover, acting early will protect PLP and other parties with mining claims in the watershed from investing additional resources in a mining project manifestly unsuited to a region like the Bristol Bay watershed. As EPA noted in 1979 in response to comments concerned that the 404(c) regulations might have a significant adverse economic impact, "the use of 404(c) may well have some economic benefits that outweigh some of the costs, through the use of pre-

M.A. Norden Veto, Final Determination of the Administrator Concerning the M.A. Norden Site Pursuant to Section 404(c) of the Clean Water Act (June 15, 1984) at 16, available at <http://water.epa.gov/lawsregs/guidance/wetlands/upload/NordenCoFD.pdf>; see also 49 Fed. Reg. 29,142 (July 18, 1984).

⁵⁸⁸ Mingo Logan Coal Co. v. U.S. Env'tl. Protection Agency, CA No. 10-0541 (ABJ) (D.D.C. March 23, 2012).

⁵⁸⁹ Id. at 12.

⁵⁹⁰ Id. at 2 (emphasis added).

⁵⁹¹ Id. at 29.

⁵⁹² Id. at 33-34.

⁵⁹³ Id. at 31. This result is not directly applicable to the petitions pending here since no section 404 permit has even been applied for – much less issued – for the Pebble Mine. NRDC believes, however, that EPA's reading of section 404(c) in the Spruce No. 1 Mine proceeding and subsequent court challenge is consistent with the statute and the Clean Water Act as a whole.

application ‘vetoes’ before industry has made financial and other commitments which lock it into a particular project design and location.’⁵⁹⁴

For reasons of statutory and judicial interpretation and economic certainty, therefore, it is not only appropriate but necessary for EPA to act proactively in exercising its authority under section 404(c). Where the environmental criteria identified in section 404(c) are met, the agency has the authority to protect the area and natural resources at risk. Delaying action in deference to the Army Corps would run contrary to the statute, to EPA’s own administrative preference (“EPA strongly prefers to initiate the § 404(c) process prior to issuance of a permit”⁵⁹⁵), and to the interest of all stakeholders in efficiency and certainty.

A reviewing court will apply a deferential standard when evaluating the legality of EPA’s section 404(c) determination. Under the Administrative Procedure Act, agency action must be set aside if it is “arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with the law,” or if it fails to meet statutory, procedural, or constitutional requirements.⁵⁹⁶ A court may not vacate an agency’s decision unless it

has relied on factors which Congress had not intended it to consider, entirely failed to consider an important aspect of the problem, offered an explanation for its decision that runs counter to the evidence before the agency, or is so implausible that it could not be ascribed to a difference in view or the product of agency expertise.⁵⁹⁷

In past cases where EPA’s section 404(c) decisions have been challenged, the courts have applied that deferential standard of review.⁵⁹⁸

⁵⁹⁴ Id.

⁵⁹⁸ City of Alma v. United States, 744 F. Supp. 1546 (S.D.Ga. 1990); Creppel v. U.S. Army Corps of Engineers, 1988 WL 70103, Civ. A. No. 77-25, 1988 WL 7010 (E.D. La June 29, 1988). As explained above, the agency has intervened under section 404(c) on thirteen prior occasions. See Riley & Yocom, Mining the Pebble Deposit, *supra* note 296, at 39-41, Table 3. Except where it did so after the final issuance of an Army Corps permit, its intervention has withstood judicial challenge. See, e.g., Bersani v. U.S. Env’tl. Protection Agency, 850 F.2d 36 (2d Cir. 1988); Alameda Water & Sanitation Dist. v. Reilly, 930 F. Supp. 486 (D. Colo. 1996); City of Alma v. United States, 744 F. Supp. 1546 (S.D. Ga. 1990); but see Mingo Logan Coal Co. v. U.S. Env’tl. Protection Agency, CA No. 10-0541

IX. CONCLUSION

NRDC applauds EPA for the quality of its scientific review and analysis contained in the draft Bristol Bay Watershed Assessment and for the comprehensive understanding that it brings to the devastating risks to water quality and the region's wild salmon fisheries unavoidably associated with large-scale mining development in the region, including the Pebble Mine. Because public review and comment have now been completed on the draft Watershed Assessment and peer review is underway,⁵⁹⁹ the agency will soon have a full factual record on which to base regulatory action under section 404(c).

EPA's Watershed Assessment, as well as the many other studies of the area, provide more than enough information to find with absolute certainty that large-scale mining in Bristol Bay would risk enormous harm to the resources protected by section 404(c). As described in detail above, a mine would cause (i) *inevitable* destruction and modification of salmon habitat and populations, as well as harm to the wildlife and native communities that rely on them; (ii) *likely* habitat fragmentation and extirpation, and chemical, acid, and metal exposure, and (iii) significant risk of *catastrophic* tailings dam failure. This is true even within the framework of EPA's conservative underestimation and exclusion of important and likely larger impacts, such as secondary development, construction and operation of a Cook Inlet port, undervalued tailings magnitude and runout distance in the case of an impoundment failure, and climate change.

Precise final design details for a proposed Pebble Mine would do nothing to lessen the significant risks described in EPA's Watershed Assessment or to alter in any material way its conclusions. As NDM has itself described in formal applications and reports, the Pebble Mine would comprise both an underground block caving mine at the Pebble East Deposit and an above-ground open pit mine at the Pebble West Deposit and would destroy over 9,200 acres of habitat.⁶⁰⁰ Assuming development only at a reduced scale, the open pit mine is projected to span over 2 miles and reach a depth of 2,500 feet.⁶⁰¹ Even at that scale, the Pebble Mine would be one of the largest mines in the world and the largest open pit mine in North America.⁶⁰² Tailings dams would be constructed to store 2 billion tons – and, more likely, more than 10 billion tons – of mine tailings in perpetuity.⁶⁰³ The mine will remove up to 35 billion gallons of water annually from wild salmon habitat.⁶⁰⁴ The maximum mine size as described in the EPA Assessment – the

(ABJ) (D.D.C. Mar. 23, 2012) (reversing EPA veto issued two years after final Army Corps section 404 permit had been granted). In James City Cnty. v. U.S. Env'tl. Protection Agency, 12 F.3d 1330 (4th Cir. 1993), the Fourth Circuit ultimately upheld EPA's decision to veto a dam permit issued by the Army Corps of Engineers after a series of remands. See 758 F. Supp. 348 (E.D. Va 1990) (overturning EPA's veto), 955 F.2d 254 (4th Cir. 1992) (affirming in part and remanding). On remand, EPA again vetoed the permit and the veto was again challenged. See 1992 WL 315199, 23 Env'tl. L. Rep. 20,228 (E.D. Va. Aug. 5, 1992) (overturning EPA's veto). On final appeal, the Fourth Circuit reversed, concluding EPA's veto decision – which was based on harm to existing fish and wildlife species, damage to the ecosystem, destruction of wetlands, and inadequate mitigation – was not arbitrary and capricious. See 12 F.3d 1330 at 1339.

“most likely” mine to be economically worthwhile, and based on the Wardrop report⁶⁰⁵ – equals or even underestimates these figures. Given these magnitudes, EPA does not need a design blueprint or a formal mine permit application to evaluate the environmental consequences of a mining project in the Nushagak and Kvichak drainages. Mining development at such a scale – whether the “minimum” or the “maximum” scenario considered by EPA – cannot proceed in this watershed without dramatically compromising the region’s physical, chemical, hydrological, and biological integrity.

By acting proactively to conduct the Watershed Assessment, and now continuing to do so through the initiation of 404(c) proceedings, EPA can achieve what it describes as “comprehensive planning rather than piecemeal decision making.”⁶⁰⁶ Addressing this issue at the front end – before permitting begins in earnest and before mining interests devote even more resources to mine development – is practical, procedurally and legally responsible, and scientifically sound. It promotes long-term clarity for large-scale metallic sulfide mining projects in the region, adheres to legal precedent that pre-permitting 404(c) review is authorized (and possibly required), and reflects good government practice by ensuring that an otherwise piecemeal approach to mining in the region does not unfairly disadvantage individual applicants or allow unavoidably risky projects to slip through the cracks.

We submit these comments to the Watershed Assessment in support of EPA’s well-researched and thorough review of the environmental impacts and risks associated with mining in the Bristol Bay region. The Assessment, and the record on which it is based, document the unacceptable adverse impacts that large-scale mining would have on the Watershed, on Bristol Bay itself, and on the communities and people most directly affected. EPA has the authority and the responsibility to prevent the certain devastation that its Assessment describes. If ever there were a case for the exercise of the agency’s 404(c) authority, it is this one.

For all of these reasons, we respectfully urge EPA, once its peer review process has been completed, to initiate proceedings expeditiously thereafter to grant the pending petitions for relief under section 404(c) of the Clean Water Act.

Respectfully submitted,

Joel R. Reynolds
